The 23rd World
Congress of Soil Science

# The 23rd World Congress of Soil Science

# Proceedings

June 7–12, 2026 Nanjing·China

## Organizers:

International Union of Soil Sciences

SOIL SCIENCE SOCIETY OF CHINA 中国土壤学会

## Hosting Institution:

中国科学院南京土壤研究所 ISSCAS Institute of Soil Science, Chinese Academy of Sciences

## Organizing Committee:

## Scientific Committee:

Jiabao Zhang (China) - IUSS Vice President Congress (2022-2026)

Victor Okechukwu Chude (Nigeria) - IUSS President

Edoardo A.C. Costantini (Italy) - IUSS Past President (2023-2024)

Bruce Lascelles (UK)- IUSS President Elect

Yongguan Zhu (China) - IUSS Division 4, 1st Vice Chair

Renfang Shen (China) - Chair of IUSS Division 3

Xiaoyuan Yan (China) - IUSS Division 2, 1st Vice Chair

Xin Song (China) - IUSS Division 4, 2nd Vice Chair

Andreas Baumgarten (Austria) - IUSS Treasurer

Cristine Morgan (USA) - IUSS Committee on prizes and awards

Kye-Hoon 'John' Kim (South Korea) - IUSS Committee on budget and finance

Cornie Van Huyssteen (South Africa) - IUSS Committee on statutes and structure

Rainer Horn (Germany) - IUSS Committee on presidential elections

Richard Heck (Canada) - Chair of IUSS Division 1

Giuseppe Corti (Italy) - Chair of IUSS Division 2

Claudio Zaccone (Italy) - Chair of IUSS Division 4

Ganlin Zhang (China)- IUSS Division 1, 1st Vice Chair

Ying Zhang (China)- IUSS Division 1, 2nd Vice Chair

Jianming Xu (China) - IUSS Division 2, 2nd Vice Chair

Fusuo Zhang (China) - IUSS Division 3, Vice Chair

Michael L. Thompson (USA) - SSSA Past President

## Advisory Committee:

D.L. Sparks (USA) - IUSS Past President (2002-2006)

R.S. Swift (Australia) - IUSS Past President (2006-2010)

Jae Yang (Korea) - IUSS Past President (2010-2014)

Rainer Horn (Germany) - IUSS Past President (2015-2016)

Rattan Lal (USA) - IUSS Past President (2017-2018)

Takashi Kosaki (Japan) - IUSS Past President (2019-2020)

Laura Bertha Reyes Sánchez (Mexico) - IUSS Past President (2021-2022)

James M. Tiedje (USA) - SSSC Foreign Fellow

Jianmin Zhou (China) - SSSC Fellow

Taolin Zhang (China) - SSSC Fellow

## Executive Committee:

Wei Hua, Xiaoyuan Yan, Xin Song, Irene Fabbri, Rong Li, Xiaopeng Li, Jiangtao Qin, Jianbo Fan, Ruijuan Sun, Jing Song, Mao Ye, Linzhou Liang, Changlong Wei, Ying Teng, Yisheng Zhang, Weidong Yan, Jinlong Dong, Lingbo Zhou, Feifei Tang

# Contents

# 101 Soil Morphology and Micromorphology ..... 1

## Session 101001: Advances in Soil Morphology and Micromorphology: Unveiling the Earth's Hidden Resource ..... 1

The Comparative Investigation of Soil Morphological Organization in Polar Urals (Yamal, Russia) and Qilian Mountains (Qinghai-Tibet Plateau, China) ..... 1

Quantitative analysis of soil erosion crack dimensions caused by wind-driven rainfall using image processing ..... 2

Preferential spatial co-location of organic matter with identified mineral phases in intact soil microstructures ..... 3

Morphological Characterization and Mapping-Based Classification of Soils in Two Locations in Southwest Nigeria ..... 4

Identification of Key Factors for Soil Drainage Classification via Color Metric Comparison from Soil Images ..... 5

Arbuscular mycorrhizal fungi hyphal density rather than diversity stimulates microbial necromass accumulation after long-term Robinia pseudoacacia plantations ..... 6

Predicting the interaction of a coated moldboard plow and soil compared to the conventional one using adaptive neuro-fuzzy inference system (ANFIS) ..... 7

SEM–EDS and Micromorphological Evidence of Kaolinite–Hematite Interactions in Ferruginous Duricrusts from Devonian Sediments of the Parnaíba Basin (Central-North Brazil) ..... 8

Segmentation-Guided Conditional Diffusion with Optical Flow Constraints for 3D Interpolative Super-Resolution of Soil CT ImagesZ ..... 9

Proto-soils of extreme environments: understanding chemical composition at a microscale with the use of Raman spectroscopy ..... 10

IUSS Digital Soil Thin Section Collections Working Group ..... 11

Soil Profile Characteristics and Vertical Stratification Beneath Nabkhas in the Coastal Deserts of Oman ..... 12

Micropedology and Artificial Intelligence – evolution of quantitative approachs ..... 13

**Session 101002: Micromorphology as a Tool for Understanding the Evolution of Soils and Environments in Natural and Human-Impacted Landscapes ..... 14**

Monitoring spatial changes in soil organic carbon in response to land-use and slope direction ..... 14

Integrating Micro- and Submicromorphological Data for Diagnosing Redoximorphic Conditions in Soils of Topographic Depressions in the Oka-Don Lowland ..... 15

Final stage of loess accumulation in the periglacial zone of the Northern Caspian region. ..... 16

The Micromorphology of Brazilian Oxisols (Latossolos): variability and fertility connections of the most representative agricultural soil in the tropics ..... 17

Stepped Canal and Levigation Pools in Teotihuacan, a study through their micromorphological and hydraulic relationships ..... 18

Micromorphological Insights into Intra-Urban Spatial Dynamics: A Case Study from Oudenaarde (Belgium) ..... 19

Long-term nitrogen fertilization effects on soil mineralogy and micromorphology: The Magruder Plots ..... 20

Quaternary landscape dynamics of the Venetian Pre-Alps (NE Italy) revealed through paleosols micromorphology ..... 21

Medieval Urban Cultural Layers in Contrasting Arid and Humid Waterlogged Environments: Morphological and Chemical Properties, and Genesis ..... 22

Formation and Evolution of Volcanic Soils in Central Apennine Mountains (Molise, Italy) ..... 23

Micromorphological mechanisms reveal 45-year Anthropogenic barrier layer formation in Northeast China's Black Soil Region: pore connectivity collapse drives sustainable management imperative ..... 24

Micro-scale pedogenic features in cold volcanic soils of Iceland: evidence from thin sections and SEM-based microanalysis ..... 25

Micro-morphological characterization of dry-farming soils at Yangshao site in China ..... 26

Species-Specific Impact of Earthworm Ecological Groups on Soil Coprolite Physico-Chemical Properties and Microstructure ..... 27

Microscopic morphological characteristics of the Albic horizon in the Black Soil Region of Northeast China ..... 28

# 102 Soil Geography/Soil Genetic Classification and Soil Geography ..... 29

## Session 102001: Magnetic Enhancement of the Soils in Urban/Industrial Areas: Sources and Properties of Anthropogenic Magnetic Particles and Its Influences on Soil Genesis ..... 29

Magnetic properties and geochemical elements, climate change in loess/paleosol from the eastern Chinese Loess Plateau ..... 29

Mineral magnetic characterization of surface soil in an industrial area within Guangzhou city: Implications for heavy metal pollution monitoring ..... 30

Study on Optically Stimulated Luminescence Dating and developmental model of alpine meadow soil in ThreeRiver Headwater Region ..... 31

Impacts of Vehicular Non-Exhaust Emissions on Magnetic Enhancement and Heavy Metal Accumulation in Urban Road Dust ..... 32

Vertical distribution of magnetic property of urban soil profiles in Shanghai and its environmental implications ..... 33

Magnetic Characteristics of Typical Soils in Guangdong Province and Their Responses to Parent Materials and Land Use ..... 34

**Session 102003: Soil Structure and Ecosystem Functioning in Earth's Critical Zone ..... 35**

Redefining soil structural vulnerability to enhance ecosystem services in a changing world ..... 35

Viral Diversity in Different Types of Purplish Soils ..... 36

Silicon cycling model and its roles on soil evolution in a subtropical critical zone ..... 37

Prediction of Soil Structural, Hydraulic, and Chemical Properties: A Comparison of NIR and MIR Across the Critical Zone ..... 38

Implications of land uses and land cover conversion on soil quality in the Lower Alwero watershed Gambela Region Western Ethiopia ..... 39

Analysis for structure of soil layer composed of large clods using X-ray CT image ..... 40

Microstructural controls on carbon cycling and nematode communities across land-use agroecosystems and climate scenarios ..... 41

Straw incorporation mitigates polyethylene residual film-induced suppression of fungal necromass ..... 42

Geodiversity-Driven Patterns of Prunus ledebouriana in Tarbagatay Mountain Landscapes of SE Kazakhstan ..... 43

Seasonal Soil Hydraulic Function and Pore Size Dynamics throughout Cover Crop–Corn Rotation in a Reduced-Tillage System ..... 44

Multifractal scaling of soil particle size distribution validates aggregate stability and pedogenic processes along a semi-arid erosional gradient. ..... 45

Co-applying straw biochar with green manure promotes rice yield and soil C, N stocks by increasing stability of macroaggregate and its associated C, N allocations in reddish paddy fields ..... 46

Microbiomes hold the key to build up high soil fertility beyond organic fertilization ..... 47

Size – Specific Effects of Intra-Aggregate Pore Size Distribution on Soil Aggregate Stability ..... 48

Spatial heterogeneity shapes enantioselective horizontal transfer of antibiotic resistance genes by pydiflumetofen in agricultural soils ..... 49

Effects of Increased Temperature, Elevated $CO_2$ Concentrations and Drought on Soil Structure and Gas Diffusion in a Submontane Grassland Soil. ..... 50

Evolution of SRO Fe oxides in soils along a paddy field chronosequence: A Fe isotope perspective ..... 51

Assessing Soil Function Loss in Traditional Gold Mining Landscapes UsingFunction-Based Soil Quality Indicator Models ..... 52

Pore-Scale Insights into Water-Heat Coupling during Soil Thawing in the Black Soil Zone ..... 53

Nonstationary response evolutionary mechanisms of aggregate binding agents in Quaternary red soils during 400 years of cultivation ..... 54

Drivers of nitrification in surface soils of Oxisols and Ultisols in tropical forests of the Central Highlands, Vietnam ..... 55

Deep soil nitrate accumulation depends on the regolith structure and surface land management ..... 56

Pore-Scale Structural Regulation of Soil Carbon Mineralization during the Corn Growing Season in a Yellow-Brown Soil ..... 57

Stabilizing Soil Aggregates with Synthetic Polymers: A Wet Adhesion Perspective ..... 58

Spatial distribution and influencing factors of the argillic horizon in the Northeast Black Soil Region ..... 59

Soil aggregate stability index independent from pre-stress aggregate size distribution: A test from soils affected by the water level fluctuation in the Three Gorges Reservoir, China ..... 60

**Session 102004: Open discussion session on observed phenomena in soils and their underlying pedogenic processes: bring and share photos of your macro- and micromorphological observations and join the discussion on debated phenomena! ..... 61**

What Are Skeletans and How Do They Form? ..... 61

Abundance of Luvisols, Retisols and accompanying ‘glossic’ soils in NE Poland. Ecological implications ..... 62

Still Soil or Already Sediments: Boundary Cases with Ferrugination in Russian Nature Reserves (Smolensk Lakelike and Geyzer Valley) ..... 63

Mattic epipedon: living skin of the Tibetan Plateau ..... 64

The Umbrisol problem ..... 65

**Session 102005: Soil Survey Technology and Spectral Database ..... 66**

Environmental factors influencing soil particle size distribution and their spatial distribution characteristics in the Tarim River Basin ..... 66

Technical Approaches and Practices for Assessing Agricultural Suitability of Soils in China ..... 67

Standards and Protocols for Soil Spectral Reflectance to Enable Remote and Precision Soil Mapping ..... 68

Building a National Soil Spectral Library from China's Third Soil Survey ..... 69

The National Soil Archive of China ..... 70

Soil Type Prediction Based on Soil Formation Factors and Random Forest ..... 71

Construction of Hainan Soil Spectral Library Driven by Large Model and Mapping of Organic Matter at 30m Resolution ..... 72

Effects of Soil pH on Spectral Inversion of Soil Organic Matter in Survey-Based Soil Spectral Libraries ..... 73

A Global Transformer Framework for Aligned Soil Spectral Analysis Across Sensors and Continents ..... 74

Toward Global Soil Spectral Interoperability: Domain-Invariant Latent Embeddings with Federated Learning ..... 75

A Novel Soil Type Inference Method Using AI Large Language Models ..... 76

The 3rd National Soil Survey of China: Integrating the Past and the Future ..... 77

Uncovering the spatial heterogeneity and drivers of grassland soil quality in Northwest China ..... 78

Hydraulic Properties of Artificial Soil Constructed from Agricultural and Forestry Waste ..... 79

# 104 Soil Classification ..... 80

## Session 104002: Classification Systems for the Anthropocene and Human-Made Soils ..... 80

Investigating the Dry Color Requirement for Mollic and Umbric Horizons ..... 80

The definitions of field characteristics in the WRB Field Guide ..... 81

Achievements and challenges for international classification of human-transformed and human-constructed soils ..... 82

Reassessment of the anthropogenic soil's classification of Slovakia - basic principles and criteria ..... 83

Soils constructed and transformed by different cultures in the Mexico Basin: from the Teotihuacans to the Aztecs ..... 84

History of the concept of Technosols, and other soils in urban areas ..... 85

Extending Technosols? The status of human-transported materials in soil classification . 86

Proposals for Urbic Technosols in World References Base ..... 87

Characterization and Classification of Soils on Sedimentary Parent Rock in Kobape, Southwestern Nigeria ..... 88

The classification Salt-affected Soil in Reclaimed Agricultural Tide ..... 89

Identifying Lithic Discontinuities in Volcanic Soils Using Particle-Size Analysis: A Comparative Study of Andosols and Nitisols Along a Toposequence in Western Java, Indonesia ..... 90

Towards Better Classification of Human-Altered Soils In WRB: a Systematic Framework and New Qualifiers ..... 91

Research on the classification of human-altered soils in China ..... 92

The rationale behind the revision of the German Soil Systematics ..... 93

Soil characterization as a tool for sustainable soil management in the Assam-Meghalaya foothill belt: Implications for humanity's shared future ..... 94

Soil classification as a carrier of functional information in viticultural terroir: linking pedogenesis and wine metabolomics ..... 95

Appraisal of Soil Taxonomy and the World References Base for Soil Resources Applied to Classify Purple Soils from the Eastern Sichuan Basin, China ..... 96

Towards a simplified key and groupings of the World Resource Base for Soil Resources (WRB) ..... 97

Soils of stone-wall bench terraced anthroscapes: A proposal for their classification ..... 98

Differences in chemical properties and soil classification of Andosols under varying volcanic ash deposition in the caldera rim of Mt. Aso, Kyusyu Islands, Japan ..... 99

# 105 Pedometrics ..... 100

## Session 105001: Advancing pedometrics ..... 100

AI Multiagent Systems as Partners in Discovery and Knowledge Synthesis for Soil Science Research ..... 100

Climate and Land Use Independent Modelling of Soil Carbon Stocks ..... 101

Pedological controls reshape global projections of soil respiration and soil carbon–climate feedbacks under climate change scenarios ..... 102

Use of Geophysical Methods for Mapping Eucalyptus Root Systems in Different Soil Types ..... 103

Exploring the controlling factors of soil spatial heterogeneity with high-resolution environmental covariates:A case study of wildfire-affected and reclaimed artificial forests in Japan ..... 104

The Uncertainty of the Carbon Sequestration Potential of Arable Soils in European Russia at different scales ..... 105

Field-scale prediction of black soil thickness based on wavelet decomposed components and multi-model validation ..... 106

# 106 Paleopedology ..... 107

## Session 106003: Reading Soil Memory Across Geological Timescales: Traditional Insights and Novel Approaches ..... 107

Climate Variability: Bridging Time Scales in Soil Formation Analysis ..... 107

Podzols of the north of Western Siberia – the bridge between modern soil formation and paleocryogenesis ..... 108

How Periglacial Past Affected the Evolutionary Pathways of Holocene Temperate Soils: Northern Part of the East European Loess Belt ..... 109

Informational role of buried Podzols in reconstruction of Holocene pyrogenic activity: a case study of Northern European Russia ..... 110

Paleosols and Their Classification in US Soil Taxonomy ..... 111

Geochemical signatures (pXRF) of polygenetic soils in the Cerrado-Caatinga transition, Piauí, Brazil ..... 112

Deciphering the Construction of the Ancient City of Palenque and its Effects on the Landscape ..... 113

New findings from the Baix loess profile (Rhône Rift Valley, southern France) in the climatic transition zone between Central and Southern Europe ..... 114

Earthen archaeological sites as archives of information on the evolution of soils and paleoclimate of the second half of the Holocene, dry steppe zone, Southern Cis-Urals, Russia ..... 115

Bronze Age kurgans as a complex paleoarchive: data from paleosoils and kurgan constructions in the steppe zone of Russia ..... 116

Pedogenic Response to Holocene climatic fluctuations in the Caucasian foothills (Dagestan, Russia). ..... 117

Acid sulphate pedogenesis of the geological past of the Earth and beyond it ..... 118

Indicators of the paleoecological situation in the Volga region soils ..... 119

Paleosols as a key for piecing together the past climates and the intricacies of soil processes ..... 120

Reading the Quaternary Soil Memory: Quartz Isotope Fingerprints of Aeolian Processes in the Asian Steppe ..... 121

More than a metaphor: soil memory as methodological framework ..... 122

Paleoenvironmental significance of earthworm aestivation chambers from Cretaceous paleosols ofAraripe Basin, Brazil ..... 123

Testing the Transferability of Paleosol Geochemical Proxies in Tropical Maastrichtian Climates: Evidence from India ..... 124

Distribution, characteristics, and formation mechanism of siliceous restrictive layers in the black soil region of Northeast China ..... 125

Revisiting krotovina formation using luminescence dating - a case study from NE China ..... 126

The basalt – laterite sequences in the Leizhou Peninsula, South China: Indicating multiple alternations between volcanic eruption and laterite formation in the tropical region since the Middle Pleistocene ..... 127

The Final Stage Of Loess Accumulation In The Glacial Region Of The Last Glaciation And Its Reflection In The Properties Of Modern Soils: A Case Study Of Northwestern Russia. ..... 128

Palaeobotanical records from soil infill of rodent burrows reveal Mid- to Late-Holocene environmental dynamics: A case study from the central chernozem region of Russia ..... 129

Climate-driven silicate weathering and biogeochemical coupling in black soils ..... 130

Radiocarbon dating: new approaches in soils and paleosols – are these new opportunities or problems? ..... 131

# 107 Permafrost Affected Soils ..... 132

## Session 107001: Permafrost-Affected Soils of the Changing High-Latitude and High-Altitude Environments ..... 132

Soil-Permafrost Complexes of the Russian North-East Arctic Accumulative Sea Coasts: Structure, Properties, Diagnostics, Ecological Functions ..... 132

Suggestions for Classifying Soils of the Retrogressive Thaw Slumps Impact Zone in Future Russian and International Soil Taxonomies ..... 133

Spatiotemporal Variations of Soil Hydrothermal Processes and Their Association with Mattic Layer Rupture in Alpine Soils on the Qinghai-Tibetan Plateau ..... 134

Structural Features of Soils and Upper Permafrost of Eastern Chukotka Coastal Plains 135

Wildfires accelerate permafrost area loss via reducing soil organic matter ..... 136

The $CO_2$ and CH4 fluxes from the epiphytic lichen Evernia mesomorpha collected in boreal forest underlain by cryosols ..... 137

Greenhouse gas fluxes by the epiphytic lichen Bryoria in response to projected moisture increase in boreal forests underlain by thawed permafrost soils ..... 138

Enzymatic activity in podzols of the north of Yamalo-Nenets Autonomous Okrug ..... 139

Landscape Conditions of Soil Formation in Drained Lake Basins of the Russian European North ..... 140

Features of Soil Formation in Khasyreys (Tundra Thermokarst Depressions) ..... 141

Freeze-Thaw-Driven Soil Moisture Return Significantly Contributes to Spring Phenology on the Warming Qinghai-Tibet Plateau ..... 142

Transformation of Soil Organic Matter in Agricultural Soils in Subarctic Climatic Conditions ..... 143

Greenhouse Gas Fluxes from Different Species of Epigeic Lichen Species on Arctic Tundra Cryosols ..... 144

Contrasting Geochemical Signatures of Groundwater and Peatland Waters in Permafrost Bogs of the European Russian Northeast ..... 145

Environmental controls on soil organic matter composition across a glacial-landscape gradient: A case study of debris-covered glaciers in Gongga Mountain, southwest China ..... 146

Minerals and Peroxidases Regulate Soil Carbon Stability in Permafrost ..... 147

Heterogeneity of cryogenic soil cover related to development of patterned ground of Kolguyev Island (Barents Sea) ..... 148

Needle ice - an antigravity mechanism of cryogenic transformation of soils ..... 149

Soils of European Arctic cities under climate change ..... 150

Assessment of Carbon Stocks in Soils ofthe Western Siberian North ..... 151

Climate-Induced Changes in Soil-Forming Factors and Processes in Permafrost-Affected Areas: Positive and Negative Trends (A Review) ..... 152

The Soil Factors of Palsas Resilience in an Industrial Wasteland in the Arctic Region (Monchegorsk, Russia) ..... 153

Characterizing Pan-Arctic Soil Organic Carbon: A Comprehensive Database of Particulate and Mineral-Associated Fractions ..... 154

Vertical Distribution of Methane Concentration in Permafrost-Affected Soils of Central Yakutia ..... 155

Assessment of soil temperature dynamics in different soil landscapes in western Greenland ..... 156

Soil structural transformation under multiple freeze-thaw cycles with comprehensive morphological and topological analysis: the hypothesis of periodicity ..... 157

Organic-matter rich soils hidden inside alpine periglacial blockfields: paleosols or aeolian deposits? ..... 158

Soil organic carbon stock assessment in cryoturbated turf/grass mounds in Kobresia Medows, Qinghai-Tibetan Plateau) ..... 159

Mattic layer ruptures in the Third pole: mechanisms, distribution, consequences, and monitoring ..... 160

# 108 Digital Soil Mapping ..... 161

## Session 108001: Advances in Remote Sensing for Soil Property Mapping . 161

Study on the coupling relationship between agricultural water and soil resources carrying capacity and grain production capacity in typical black soil regions of Northeast China 161

Study on the coupling relationship between agricultural water and soil resources carrying capacity and grain production capacity in typical black soil regions of Northeast China 162

Integrating Remote Sensing and Soil Drainage Mapping to Predict Salinization Risk ... 163

Geostatistical fusion of field and remote sensing data for assessing soil salinity in southern region of Morocco ..... 164

Study on Soil Organic Matter Inversion of Different Textural Soils in the Northeast Black Soil Region Based on Hyperspectral Remote Sensing ..... 165

An airborne platform for enhanced soil characterization ..... 166

Intelligent Monitoring of Soil Salinization by Integrating Agronomic Features ..... 167

Integrating UAV-Mounted Gamma-Ray Spectrometry and Soil Laboratory Analysis to Characterize Sediment Erosion, Composition, and Pollution in Vineyards ..... 168

Soil Reflectance Composite and Terrain Attributes for Digital Soil Mapping in a Mediterranean Cropland District ..... 169

Localized SCORPAN-based machine learning framework for spatial-temporal tracking (2000–2025) of soil carbon dynamics in Chile ..... 170

Accurate Time-Series Retrieval of Soil Salinity from CYGNSS Data by Physics-Based Surface Correction and Semi-Empirical Model ..... 171

Explainable Deep Learning Unveils Critical Scenarios Driving Soil Cadmium Pollution in a Coastal Industrial City: A Geospatial AI Approach ..... 172

Advancing Corn Yield Prediction through Cross-Scale Integration Approaches ..... 173

Enhancing Precision Nitrogen Management through Integration of Soil Properties and Remote Sensing ..... 174

Geospatial Index of Acid Mine Drainage (IIMSDAM) Impact on Soils ..... 175

Multi-view hyperspectral feature can improve soil property retrieval ..... 176

Physically supervised harmonic framework for spatial characterization of apparent soil thermal diffusivity between 5 and 10 cm. ..... 177

A Meta Learning Framework for Spatio-temporal Mapping of Cropland Topsoil pH in Southern China ..... 178

Differentiating parent materials using the soil thermal gradient between 5 and 10 cm at national scale (Uruguay) ..... 179

Mapping Soil Salinity with Satellite Embeddings and Environmental Covariates ..... 180

Spatiotemporal Dynamics and Uncertainty Attribution of 1 km Satellite Soil Moisture Products Across China: A Comparative Assessment via TCH and OPGD ..... 181

A Property-Dependent Strategy for Digital Soil Mapping: Optimizing Sentinel-2 Time-Series for Stable and Dynamic Soil Attributes ..... 182

**Session 108002: Democratizing Digital Soil Mapping: Innovative Technologies for Global Soil Services and Solutions ..... 183**

Innovation in Large-scale Soil Pollution Investigation Driven by Multi-source Data: A Transition from Grid-based to Precision-based Approaches ..... 183

The spatiotemporal variation in soil inorganic carbon ..... 184

A Zonal Optimization Mapping Framework for Soil Taxonomic Classification in Large Flat Regions: A Case Study of the Songnen Plain ..... 185

Future Projections of Global Belowground Net Primary Productivity in Response to Climate Change ..... 186

A Multi-Source Product Assessment and Uncertainty-Aware Modeling Framework for SOC Mapping in China ..... 187

Innovative Technologies for European and Global Soil Services and Solutions - SoilWise Project Achievements ..... 188

Predicting Textural Classes Using GPR-derived Geophysical Data and Optimized Machine Learning in Subtropical Forests ..... 189

Integrating Proximal and Remote Sensing to Cross-scale Quantify Soil Organic Carbon and Moisture Dynamics via Multi-model Learning ..... 190

Warming and Drying Patterns across Iran: A Three-Decade Remote Sensing Perspective on Land Surface Temperature, Soil Moisture, and Vegetation Dynamics ..... 191

SOCBIO-MAP: Integrating Earth Observation, AI, and In-Situ Sampling to Democratize High-Resolution Soil Organic Carbon and Biodiversity Mapping ..... 192

Digital Soil Mapping Plus Complexity Analysis: an Effective Approach to Identify Sensitive Areas of Landscape Evolution ..... 193

Projected intensification of soil salinization in global drylands under future aridity increase ..... 194

Spatial distribution and formation environment of rock fragment layer in black soil region of northeastern China ..... 195

UAV assisted high-resolution mapping of soil organic carbon and nitrogen in the mattic layer of the Tibetan alpine meadow ..... 196

## Session 108003: Leveraging Site and Spatial Data for Soil Monitoring.....197

Development and Applications of a Soil Spectral Library in Hainan, China ..... 197

From Mars to Farmland: Next-Generation In-Situ Soil Composition Monitoring Technology for Agricultural Fields ..... 198

Stacking ensembles with spatial residual correction for improved soil pH mapping in tropical croplands ..... 199

Standardized Soil Water Deficit Index for Monitoring Agricultural Drought in India with a Machine Learning Extended Root Zone Soil Moisture Dataset ..... 200

Soil Fertility Index and Spatial Variability as Drivers of Site-Specific Fertilizer Management in the Tigray Highlands ..... 201

Well-facilitated Farmland Construction enhances soil organic carbon storage in China 202

Spatiotemporal divergence of soil acidification in China's cropland ..... 203

Global hotspots of soil microplastics and their drivers ..... 204

Assessing human activity impacts on soil nutrient condition in Australia. ..... 205

WoSIS: An international effort to share standardised soil data for the world ..... 206

Low-Cost Sensors for Monitoring Soil Condition in Landscape Restoration ..... 207

Using legacy data and geostatistics for assessing soil organic change in the Sele River Plain (southern Italy) ..... 208

Quantifying Pan-European Soil Organic Carbon Trends and Associated Uncertainty for Soil Health Monitoring ..... 209

Modeling of spatiotemporal heterogeneity of agrochemical properties of soils within the territory of testing agricultural crop varieties ..... 210

Measuring Ephemeral Gully Morphology Using a Portable Gulliometer and Image- based Techniques ..... 211

A streamlined soil database strengthening near-real-time interoperability for soil monitoring networks and services ..... 212

Step towards a 1:100,000-scale Soil Map of Italy supporting the implementation of a national soil monitoring network and service ..... 213

Reshaping Cropland Quality Monitoring through the Rational Use of Crowdsourced Data ..... 214

Spatio-temporal patterns and environmental controls of soil organic carbon stocks in global tidal wetlands since 2009 ..... 215

Estimation of Salinization in the Yellow River Delta Based on BO-XGBoost and a Four-Dimensional Feature Space, with Spatiotemporal and Trade-off/Synergy Factor Analysis ..... 216

Interpretable salinization estimation model for Dongying City based on integrated multi-dimensional spectral indices with XGBoost-driven transformations ..... 217

Soil Salinity Inversion in the Yellow River Delta Based on BO XGBoost and 3D Spectral Feature Space ..... 218

**Session 108004: Operational Digital Soil Mapping: Fitness for Use of DSM Products: Pitfalls to Avoid and Way Forward ..... 219**

Mapping and validating the root zone plant-available water holding capacity in central Ethiopia ..... 219

Characterisation of global and continental DSM products: beyond point accuracy and towards user needs ..... 220

Beyond uncertainties: making standalone metrics decision-oriented through game theory ..... 221

From Legacy Soil Maps to Fit-for-Use DSM Products: A Case Study from Portugal ..... 222

Transposability of MUSE (French DSM method for the Evaluation of Soil Multifunctionality) to EU scale in the framework of EU-funded Horizon Europe SPADES project ..... 223

Digital Soil Mapping of pH at European scale: comparing national vs. continental inputs ..... 224

National soil information grids of China: problems and possible solutions ..... 225

Assessing quality gains from physically supervised harmonic fitting for apparent soil thermal diffusivity estimation. ..... 226

Landscape-scale Detection of the Spatio-temporal Variations of Soil Total Nitrogen and Its Influencing Factors in a Grassland by Soil Mapping ..... 227

Revealing the landscape with Digital Soil Mapping ..... 228

**Session 108005: Digital Soil Mapping and Assessment: Advances, Applications, and Future Directions ..... 229**

Applying Digital Soil Assessment to Support the Effectiveness Evaluation and Design Optimization of Buffer Strips ..... 229

Determination of the Cultivated Land Quality Red Line in Northeast China ..... 230

Mapping Spatiotemporal Soil Temperature in Real-time using Neural Networks Combined with Heat Transfer Equation ..... 231

New dimensions of farmers' decision making: Demonstration of a 3D web-viewer for erosion mitigation strategies ..... 232

Continental-Scale Soil Assessment in Africa: Design, Implementation, and Early Findings from Soils4Africa ..... 233

Mapping of bundles of soil-based ecosystem services in the European Union and their evolution by 2050 ..... 234

Intelligent Mapping Paradigm to Overcome Systematic Bias in Remote Sensing SOC Estimation: A Case Study of the Black Soil Region in China and the United States ..... 235

Spatial Variability of Soil Acidity and Mapping of Selected Soil Properties in Chancho Micro Watershed, South western Ethiopia ..... 236

Assessing the carbon sequestration potential and identifying influential factors of cultivated soils in Northeast China ..... 237

Three-dimensional soil organic carbon stocks in Tibet, China: spatial heterogeneity, driving factors, and future Changes ..... 238

Soil organic carbon in Chinese grassland ecosystems: spatial heterogeneity, driving factors, and future changes ..... 239

Spatio-Temporal Variations in Soil Organic Carbon Stocks in Different Erosion Zones of Cultivated Land in Northeast China Under Future Climate Change Conditions ..... 240

Digital mapping of Solonetz within forest-steppe landscapes of the Oka-Don Lowland 241

Comparative Study on Soil Spatial Provenance Based on Soil Property Similarity Clustering and Pedogenic Environment Inference ..... 242

Integrating Hierarchical Factor Analysis and Digital Soil Mapping to Update Legacy Maps and Identify Soil Carbon Loss Hotspots for Land-Use Policy ..... 243

Spatially-Explicit Uncertainty and Feature Attribution in Landscape-Scale Topsoil Carbon Mapping in Forest-Steppe ..... 244

Integrating Digital Soil Mapping and Remote Sensing–Based Soil Moisture for Crop Water Requirement Modelling at the Land Parcel System Scale ..... 245

Model Selection for Digital Soil Mapping Using Spatial Structure Indices ..... 246

Enhancing Regional Topsoil Total Nitrogen Mapping through Differentiated Fusion of Ground Hyperspectral Data and Satellite Images Under Low Vegetation Cover ..... 247

Mapping Soil Particle Size Distribution: Fine Earth and Coarse Fragments ..... 248

Using Compositional Methods ..... 248

Distributional Validation of Digital Soil Maps using Aggregated Commercial Data ..... 249

Modelling and mapping land susceptibility to degradation and desertification in Europe ..... 250

# 110 Proximal Soil Sensing/Soil Remote Sensing and Information ..... 251

## Session 110001: Advances in Soil Health Monitoring with Proximal Sensing ..... 251

Soil Organic Carbon Spectral Modeling with MIR in Carbonate-Rich Soils Requires Temperature Ramping References Data for Reliable Training. ..... 251

Evaluating Portable Miniaturized NIR and Vis-NIR Technologies for Soil Spectroscopic Analysis ..... 252

Intelligent Soil Monitoring ..... 253

Evaluating Portable X-Ray Fluorescence (pXRF) for Soil Fertility Assessment: Influence of Moisture and Soil Properties ..... 254

Low-cost portable near infrared spectroscopy for in-situ and laboratory prediction of soil organic carbon in Ferrosols ..... 255

Sequential indirect modeling of soil properties from spectral data with small sample set ..... 256

Sensor-based monitoring of Soil EC responses to nitrogen and potassium fertilization under laboratory and field conditions ..... 257

Coastal Soil Salinity Inversion Using Resource Satellite Data and Explainable Machine Learning: A Case Study of Southern Laizhou Bay ..... 258

Deep Learning-Based Similarity Framework for Rapid Soil Organic Matter Assessment from Smartphone Imagery ..... 259

Preprocessing and Optimizing Sensitive Wavelength Enable End-to-End Estimation of Soil Heavy Metals using Hyperspectral Remote Sensing ..... 260

Multi-Element Synergy-Driven Transfer Learning Model for Enhancing the Generality of Soil Heavy Metal Concentration Estimating ..... 261

A transferable spatiotemporal deep learning framework integrating soil moisture dynamics for high-resolution cropland Soil Organic Matter Mapping Across Regions ..... 262

Regional bare soil mapping method integrating multi-source remote sensing data in cloudy environments ..... 263

Accuracy improvement of spatial prediction for soil organic matter using receptive field fusion module in hilly areas ..... 264

Towards Sustainable Land Use: Soil Health Assessment at a National Scale using Spectral Information ..... 265

Metagenomic tools for soil health–oriented microbial monitoring in agricultural systems in Mexico ..... 266

Improving in-situ spectral estimation of wetland soil organic carbon by integrating multiple optimization strategies ..... 267

Spatio-temporal fusion–based analysis of soil salinization dynamics in the Ningxia–Inner Mongolia Yellow River Irrigation District (2000–2025) ..... 268

SWRCI: A Novel Remote Sensing Index for Soil Water Retention Capacity ..... 269

The Accurate Estimation of Soil Available Nutrients Achieved by Feature Selection Coupled with Preprocessing Based on MIR and pXRF Fusion ..... 270

A Dataset-Based Statistical Comparison and Fusion of Gamma-Ray and Visible-Near-Infrared Sensing Technologies for Soil Texture Prediction ..... 271

Measuring Soil Health Using Technologies Across Scales ..... 272

Accuracies and costs of prediction and mapping soil properties using proximal sensors: A systematic review ..... 273

Soil drainage survey using Electromagnetic induction Sensing ..... 274

A comparative study of four color measurement methods for soil color identification and related properties prediction ..... 275

Comparison of mid–infrared and visible/near–infrared spectroscopy of moist–intact cores and dry–ground soils for soil property prediction ..... 276

Dynamic inversion of soil salinity in farmland across the Hetao Plain of China based on a spatiotemporal fusion algorithm (2000–2024) ..... 277

Monitoring soil arsenic content in densely vegetated agricultural areas using UAV hyperspectral, satellite multispectral and SAR data ..... 278

Mapping mollic epipedon thickness via ground-penetrating radar based on the combined method of Variational Mode Decomposition and Average Envelope Amplitude ..... 279

Hybrid Deep Learning for Soil Property Prediction Using Vis-NIR Spectroscopy .....280

Advancing Soil Health Monitoring Using Proximal VIS–NIR and MIR Spectroscopy Integrated with Multivariate Modeling ..... 281

Identification of Alkalized Horizons Using Ground Penetrating Radar in Typical Saline-Alkali Areas of the Songnen Plain ..... 282

Quantitative Monitoring and Inversion of Soil Moisture Content Based on Ground Penetrating Radar: Progress, Methods, and Prospects ..... 283

## Session 110003: Soil Spectroscopy: A Global Solution for Sustainable Soil Management and Food Security ..... 284

Prediction of soil organic matter using visible–near-infrared spectroscopy combined with textural hand-feel determination ..... 284

The use of low-cost spectrometers to predict key soil properties for digital soil mapping in South Sumatra, Indonesia ..... 285

Comparison of mid and near infrared spectroscopy in predicting stable isotope values (δ 13C and δ15N) of tropical soils in Madagascar ..... 286

Determination of Nitrogen in Maize Plant Using Near Infrared Spectroscopy and Partial Least Squares Regression ..... 287

A Vis-NIR penetrometer system for field measurement of soil organic carbon ..... 288

A comparative study of Random Forest and Neural Network with implementation of Boruta algorithm for predicting soil properties from Visible-Near Infrared spectra ..... 289

Transferability of Global Spectral Models for Local Soil Organic Carbon Predictions: Effects of Spiking on Model Performance ..... 290

Standardized Protocol for Soil Organic Matter Prediction using Vis-NIR Spectroscopy- A Meta-Analysis ..... 291

Carbon Assessment in Peat Soils Through Moisture-Corrected Vis–NIR Spectroscopy and Instrument Comparison ..... 292

Spectroscopic Screening of Soil Extracellular Oxidases and Their Application in Soil Health Monitoring and Carbon Modeling ..... 293

Comparative analysis of Vis-NIR and MIR spectroscopy for predicting soil properties and identifying minerals at smallholder cocoa farms across Papua New Guinea ..... 294

Estimation of Soil Inorganic Carbon Based on Visible Near Infrared Reflectance Spectroscopy Absorption Depth ..... 295

Alternative Spectroscopic Approaches for Soil Analysis: A Comparative Study ..... 296

Vis–NIR Spectroscopy and Chemometrics for Soil Pollution Assessment: Challenges and Opportunities ..... 297

Sample Transfer Learning for Improving Field-Scale Soil Organic Matter Inversion via UAV Hyperspectral Remote Sensing ..... 298

Characterization of soil organic matter regarding both the structure and composition by Fourier transform infrared attenuated reflectance spectroscopy ..... 299

Soil Profile Horizon Classification Integrating Point-Based Hyperspectral Data and Machine Learning Algorithms ..... 300

Estimation of soil inorganic carbon storage for profiles based on spectroscopy ..... 301

Effect of spectral range, spectral pre-processing, calibration method, and sample classification on soil property predictions using a country-scale soil spectral library for Hungary ..... 302

# 112 Universal Soil Classification ..... 303

## Session 112001: Advances in Numerical Soil Classification .....303

Layer–Profile Integration for Numerical Soil Classification .....303

Harmonization of Soil Typological Units Across Administrative Regions: A Case Study from Italy .....304

Transformation of Aluminum Forms During Andosol Genesis in Japan .....305

Efforts to develop modern objective numerical data sources to support universal approaches of soil classification ..... 306

# 201 Soil Physics ..... 307

## Session 201001: Beyond Plant Available Water - New Insights on Soil Water Accessibility ..... 307

Water-Microbe-Mediated Rhizosphere Microbial Communities Reshaping Agroecosystem Resilience ..... 307

Confronting Water Availability versus Water Accessibility in Plant–Soil Relations ..... 308

Physically informed Bayesian mixing models reveal more realistic root water uptake profile ..... 309

Soil-Water and Groundwater: Connections at the Food-Water-Energy Nexus ..... 310

A Complex-Plane Representation of Gas Diffusivity in Variably Saturated and Fractured Porous Media ..... 311

Modeling Water Movement in Gravity Potential Difference Irrigation Based on Hydraulic Potential Difference-Driven Outflow Mechanism ..... 312

Impact of Biosolids on Plant Available Water and Beyond ..... 313

Root zone in the Earth system ..... 314

Predawn Leaf Water Potential of Grapevines Is Not Necessarily a Good Proxy for Soil Moisture ..... 315

Water Balance and Plant Available Soil Water: Linking Soil Physics and Hydrology ..... 316

A Process-Based Proxy for the Water Availability to Plants ..... 317

Defining, monitoring, and utilizing plant available water information as a public good 318

Development of soil mechanical stability during initial soil formation – from field to rhizosphere scale ..... 319

Rhizosphere Hydraulic Regulation Across Soil Textures: Evidence for Texture-Dependent Mucilage Function ..... 320

Estimating Soil Water Matric Potential from Penetration Resistance Measurements ..... 321

A complete morphological and topological description of soil pore structure dynamics during wetting-drying ..... 322

A Mechanistic Soil-Plant Model to Assess Soil Water Accessibility ..... 323

Trees' Effect on Soil Penetration Resistance Under Livestock-Forestry System in Southern Brazil ..... 324

Creating Pathways for Roots: Artificial Macropores through Compacted Subsoils ..... 325

Modeling plant water and solute uptake by HYDRUS ..... 326

Biochar application to soil in agricultural water management ..... 327

Assessment of irrigation water consumption in the Yellow River Delta based on GIS and HYDRUS-1D ..... 328

Stress-Strain Mechanism of Salt-affected Soils in the Yellow River Delta ..... 329

Impact of drought and root excision on root regeneration, xylem hydraulics and leaf physiological characteristics in Robinia pseudoacacia ..... 330

Improvement of the Soil Water Retention Model Based on the Additivity Hypothesis .. 331

Adaptive water use strategies of artificially revegetated plants in a water-limited desert: Implications for sustainable ecological restoration ..... 332

Evolution of Salt Precipitation: Governing Water and Heat Transport in Saline Soils .... 333

Field-scale Assessments of Subsoil Compaction and Soil Structural Functions in Lower Saxony, Germany ..... 334

Soil Pore Size Distribution and Water Retention Curves by Low-Field NMR ..... 335

Collaborative roles of soil and plant hydraulic resistances in plant water transport: insights from modeling and data synthesis ..... 336

Mucilage effects on soil–plant hydraulics and stomatal regulation under drought ..... 337

Study on the Impact of River-Sea Position on Water Sources of Tamarix chinensis Vegetation in the Yellow River Delta ..... 338

HYDRUS-2D-based Study on the Impact of Drip Irrigation and Soil Compaction on Soil Water and Salt Movement ..... 339

From Laboratory to Field: Advancing Soil Heat Flux Plate Accuracy through Philip Correction and Field Calibration ..... 340

Pore systems and functions in structured soils- how far affect soil management and environmental impacts an unambiguous assignment? ..... 341

**Session 201002: Linking Physical and Hydrological Processes with Soil Health and Functionality in Terrestrial Ecosystems ..... 342**

From Sedimentation to Laser Diffraction: A New Particle Size Distribution Classification Based on Soil Mechanical Properties ..... 342

Revisiting soil water retention behavior as influenced by microbial growth under unsaturated conditions ..... 343

Optimizing implementation strategies for efficient soil water evaporation measurements with multi-probe heat pulse sensors ..... 344

Root-soil interface traits in modern and landrace barley genotypes differ in the lab but not the field ..... 345

Seasonal dynamics of soil structure and water retention of field soils with different long-term amendment rates of slurry and compost: measurements and modelling ..... 346

Modelling the relationship between naturally occurring radionuclides and grain size of sediment of various river basins, South Africa ..... 347

Construction of the Integrated Soil Database for Hydrological Modeling in Brazil ..... 348

Accurate soil thermal conductivity schemes are crucial for improved earth system modelling skill ..... 349

Applicability and transferability of the state-space approach to predict saturated soil hydraulic conductivity at watershed scale ..... 350

Cover Crops, More Than Crop Rotation Diversity, Improve Soil Porosity, Carbon Storage, and Hydraulic Conductivity in a Long-Term No-Till Field Experiment in South Dakota ..... 351

Impact of Dry-wet Cycles on Nitrogen and Phosphorus Mineralization in Soils Amended with Cattle Manure ..... 352

Biochar Effects on Soil Hydrophysical and Chemical Properties: Texture and Particle Size Matter ..... 353

In-situ determining the dynamic of soil bulk density by using the combined soil moisture and thermal property sensors in a Vertisol and its relationship with waterlogging ..... 354

Soil structure versus soil life: Microbial resilience to compaction in contrasting soil types ..... 355

Soil moisture, irrigation efficiency, and soil strength interactions under centre pivot irrigation ..... 356

Quantifying the Impact of Tractor Tire Pressure and Soil Management History on Soil Porosity and Void Morphology ..... 357

Dry-wet cycles promote microbial interactions and horizontal gene transfer ..... 358

Long-term organic fertilizer substitution alleviates the surface soil compaction of a Vertisol by improving soil structure ..... 359

Causality analysis and prediction of soil saturated hydraulic conductivity by combining empirical modeling and machine learning techniques ..... 360

Straw incorporation depth drives microbial carbon sequestration by remodeling physical habitat in Mollisols ..... 361

Estimation of soil water retention curves by combining thermal conductivity and electrical conductivity curves ..... 362

The added value of CoreVESS score, penetration resistance, and geophysical techniques in predicting and characterizing the soil–water retention curve ..... 363

Hydrodynamic Shear Stress Regulates P. aeruginosa Attachment via Motility Organelles ..... 364

Root-mediated regulation of soil infiltration dynamics in eroded Mollisols ..... 365

Controls on near-saturation water retention and structural stability of soils across four climatic regions: long-term land use versus single amendment ..... 366

An analytical solution for measuring thermal properties with heat pulse method under convective boundary conditions at the soil-atmosphere interface ..... 367

Variation in soil hydraulic properties under different land use in long term experimental plots across Canada ..... 368

Impacts of model root exudates (Pectin and Oxalic Acid) on multiscale soil structural, hydraulic, and surface properties ..... 369

Study on the Evolution of Multi-scale Pore Structure and Hydraulic Properties in the Arable Layer of Paddy Fields ..... 370

Effect of organic matter on isothermal thermogravimetric profiles in the low temperature range (60°C–200°C) ..... 371

How Water-Salt Stress Reshapes the Rhizosphere and Regulates Growth in Suaeda salsa ..... 372

Effects of long-term fertilization on soil macropore structure and hydraulic conductivity in paddy soils ..... 373

Transformation of Agro-Physical Soil Properties During Urbanization: A Case Study in the Republic of Adygea ..... 374

Nitrous oxide emissions in Argiudolls of the Central Pampas Region of Argentina managed with no-tillage and controlled traffic farming ..... 375

Bearing capacity of an Argiudoll under direct seeding and controlled machinery traffic amended with soluble calcium ..... 376

Effects of grass hedgerow measures on physical crust development and slope runoff and sediment of southern Quaternary red clay in China ..... 377

Interfacial hydrodynamic isotope fractionation of infiltrating rainfall in soil pore water is independent of evaporation ..... 378

Pore Structure–Controlled Water and Solute Transport in Agricultural Soils of Plain River Network Areas ..... 379

Microscale biophysical interactions determine environmental microbial ecology ..... 380

Effects of Different Land Uses on Soil Structure and Hydrological Function: Mechanisms and Implications ..... 381

Characteristics of Aggregates and Their Response to Nutrients in Dark Brown Soil under Different Nitrogen and Phosphorus Fertilizer Levels ..... 382

Effects of Spatial Resolution on Spectral Characteristics of Soil Salinity in Plastic-Mulched Farmland ..... 383

Sensitivity analysis of agricultural hydrological processes to climate change in the North China Plain ..... 384

Mechanical Adaptive Feedback Mechanisms of Microbial Colonies to External Physical Pressure ..... 385

Impacts of precipitation and heat changes on agricultural water resources and grain production in the North China Plain ..... 386

# 202 Soil Chemistry ..... 387

## Session 202001: Physicochemical and Biological Processes of Chemicals in Soils ..... 387

Sea weed contribute enormous number of charges to soil system and enhances massive rice productivity ..... 387

Floodplain Wetlands as Biogeochemical Filters Following Wildfire ..... 388

Potassium mineralization potentials of some soil amendments applied to a degraded tropical Ultisol ..... 389

The effect of endogenous hydrogen on the soils of the degassing sites of the Central Chernozem region of the Russian Federation ..... 390

Effects of repeated wetting and drying cycles on potassium fertiliser behaviour and nutrient dynamics in diverse soils ..... 391

Impact of Saltwater Intrusion on Phosphorus Speciation and Mobility in an Agricultural Soil ..... 392

Soil development on coal-waste dump in southern Poland ..... 393

Salix acutifolia Willd. as an ecological engineer in the processes of soil formation and plant succession in sandy areas ..... 394

Using radiogenic and metal stable isotope ratios as new tools to assess nutrient cycling in agricultural systems ..... 395

Mapping Microscale pH Dynamics at Soil–Amendment Interfaces Under Fluctuating Moisture Conditions ..... 396

Dissipation of $^{13}$C-Sulfamethoxazole in Tropical Soils under Contrasting Management Systems and Microplastic Contamination ..... 397

Understanding nutrient diffusion and availability from polyhalite fertiliser in contrasting soils ..... 398

What controls the metallomes of carrot and wheat grown under varying soil water conditions in greenhouse? ..... 399

Process-Based Multi-Surface Modeling of Soil Arsenic: Enabling Large-Scale prediction of environmental fate and Guiding Remediation Strategies ..... 400

Chemical transformation pathways demonstrating elemental sulfur effectiveness in alkaline-sodic soils ..... 401

Persistence, Transport and Transformation of Per- and Polyfluoroalkyl Substances in Soils from repeated Land Application of Biosolids ..... 402

Evaluation of Corncob Biochar Application on Soil Fertility, and Nitrogen Cycle ..... 403

Fe(II) and Organic Acid Influence Arsenic Sorption by Magnetite ..... 404

Quantifying drivers of soil acidification under pakchoi cultivation with varying nitrogen inputs in Hainan, tropical China ..... 405

Abiotic Transformation of PFAA Precursors in Soil Under Environmental Conditions . 406

Molecular modeling of natural organic matter-heavy metal cations interactions ..... 407

Size-dependent colloidal stability and transport behaviors of typical zonal soil colloids 408

Soil–Plant Isotopic Coupling in Support of PDO Agri-Food Traceability ..... 409

Effects of Phosphogypsum on Heavy Metal Mobility and Nutrient Dynamics in Saline Soil under Spring Wheat ..... 410

Iron-carbon coupling in salinized drylands ..... 411

Initial changes in soil microbial community structure after combined biochar and straw application to agricultural soil: evidence from a 180-day incubation experiment ..... 412

CONTROL AND EVALUATION OF ALUMINUM METAL COMPONENTS IN SALINE ACID SULFATE SOIL BY ECO-FRIENDLY AMENDMENTS ..... 413

Sorption and Desorption of Phosphorus in Soil: Implications for Water Quality ..... 414

A high-resolution map of urban soil pH in the megacity of Xi'an ..... 415

High resolution mapping of carbon dioxide pollution in the Xi'an megacity, using plant carbon isotopes ..... 416

Contact-Electro-Catalysis at the Iron Mineral–Water Interface: A New Abiotic Source of Environmental ROS ..... 417

Emerging Contaminants in Soil, Water, and Plant Systems: One Health Perspective ..... 418

Microbial potential to mitigate neurotoxic methylmercury accumulation in farmlands and rice ..... 419

Comparison for colloidal stability and aggregation behavior of fulvic and humic acids: effects of cations and pH ..... 420

The fate of endocrine disruptor compounds in soil. The role of humic substances ..... 421

Plant-Microbe Interactions Mediate Nitrogen Deposition Effects on Soil Carbon Cycling in a Desert Steppe Ecosystem ..... 422

Effects of Microplastic Pollution on Soil Organic Carbon Turnover ..... 423

Sulfur Dynamics Coupled with Heavy Metal Behavior under Fluctuating Redox Conditions in Paddy Soils ..... 424

Soil Biological Crusts as Key Regulators of Surface Geochemistry in Degraded Semi-Arid Landscapes ..... 425

Surface-Modified Carbonaceous Media for Enhanced Removal of Short-Chain Per- and Polyfluoroalkyl Substances from Urban Stormwater ..... 426

Diurnal Formation and Influence Mechanisms of Multi-interface Reactive Oxygen Species in a Paddy System ..... 427

Rice Growth and Yield Formation in Heterogeneous Sodic and Saline-Sodic Soils: Challenges and Management Strategies ..... 428

Machine learning-based prediction of phenanthrene accumulation and toxicity in earthworms across soils ..... 429

Selected forms of potassium in soils of the steppe and desert zones of Mongolia ..... 430

Ultrasensitive detection of trace Hg(II) in acidic conditions using DMABR loaded on sepiolite: Function, application and mechanism studies ..... 431

Novel Ball-Milled Tourmaline-Biochar Composite: Application in Heavy Metal-Contaminated Groundwater and Bottom Sediment Remediation ..... 432

Phosphorus fractions in selected soil types located on the desert and steppe zones of Mongolia ..... 433

**Session 202002: Advances in Soil Carbon Dynamics Across Scales: From Molecules to Ecosystems ..... 434**

Carbon Cycling in Soils of Northen Coastal Ecosystems ..... 434

Iron and Manganese Catalyzed Maillard Chemistry: Molecular Characteristics, Evolution Pathways, and Implications for Soil Organic Carbon Formation ..... 435

SOM stability and energy storage in soil depending on land use change ..... 436

Dual-Domain Regulation of Dissolved Organic Matter Release in Soil: The Role of pH and Calcium ..... 437

Abiotic Methane Production Driven by Soil Reactive Oxygen Species ..... 438

Controlling factors on soil organic matter stability under threat of global warming and drought in central Asian semi-arid mountain ecosystems ..... 439

Do cover crops and no-tillage reshape soil biota and organic matter across depth? ..... 440

National mapping of cropland soil pH buffer capacity and acidity debt in China ..... 441

Impact of active Al and Fe on mineral-associated organic matter in acidic to alkaline tropical to subtropical non-volcanic soils ..... 442

Insight in the characteristics of humic substances with crop straw derived organic materials amendments ..... 443

Abiotic Processes Dominate Short-Term Carbon Emissions in Sandy Soil after Soil Rewetting: Impact of Mineral and Reactive Oxygen Species ..... 444

Carbon sequestration dynamics of MAOC in the tea plantation with different ages: evidence from Fe/Al oxides and organo–mineral interactions ..... 445

Establishing trees into permanently grazed grassland to increase SOC stocks – scaling results from microbes to landscapes ..... 446

Non-linear regulation of soil organic carbon by salinization: aggregate–microbe coupling ..... 447

Interactive effects of straw and biochar reorganize humic acid molecular architecture toward coupled reactivity and persistence ..... 448

Functional Cover Crop Diversity Enhances Root-Driven Organo-Mineral Associations and Nutrient Efficiency in High-Latitude Agriculture. ..... 449

Molecular–thermal coupling of plant residue-derived organic matter mediated by clay minerals: insights from solid-state 13C NMR ..... 450

Soil organic carbon sequestration potential and stability in Solonetzic and Vertisolic soils of the North American Prairie ..... 451

Soil Organic Carbon Dynamics During Vegetation Restoration Across Dryland Precipitation Gradients Revealed by Radiocarbon Isotopes and Microbiology ..... 452

Changes in Deep-Profile Soil Organic Carbon and Influencing Factors During Planted Vegetation Restoration in Alpine Regions ..... 453

Typical mineral additions promote soil mineral-associated organic carbon sequestration: Interactions between Fe oxides and microbial-derived peptides ..... 454

Model Ecosystems as Scalable Pathways for Soil Carbon Sequestration, Productivity and Climate-Smart Land Restoration in Africa ..... 455

Arbuscular Mycorrhizal Fungi Strengthen Aggregate Protection and Reactive Fe/Al Pools to Stabilize Soil Organic Carbon in Acidic Soils ..... 456

Black Carbon Accelerates Soil Carbon Loss through Coupled Iron Redox Cycling ..... 457

Effects of Human Land Use Practices on the Binding Patterns of Organic Carbon and Iron Oxides ..... 458

Divergent stabilization controls of lignin phenols and amino sugars as biomarkers for soil organic carbon source ..... 459

Chemical pathways of soil organic carbon stabilization in Mediterranean soils ..... 460

# 203 Soil Biology/Soil Biology and Biochemistry/Soil Virus .. 461

## Session 203001: Diversity and Function of Soil Viromes ..... 461

Into the Unknown: A Continental Exploration of Viral Diversity in Australian Soils .....461

Biogeographic patterns and drivers of soil viromes .....462

Rhizosphere-triggered viral lysogeny mediates microbial metabolic reprogramming to enhance arsenic oxidation ..... 463

Twenty-Year Time Series Reveals Ecological and Evolutionary Dynamics of Viruses in a Freshwater Lake .....464

Viral cooling of $N_2O$ emissions in long-term acidified soils ..... 465

Soil viruses as key regulators of carbon sequestration and plant growth ..... 466

Microbial Community Succession in the Rhizosphere of Citrus Grandis Exocarpium in Response to Fertilization and Huanglongbing Stress ..... 467

Translational profiles reveal prokaryotic resource allocation to prophages ..... 468

Virus-prokaryote interactions assist pollutant removal in constructed wetlands .....469

Ciprofloxacin- driven purifying selection on viral genomes accelerates soil N2O production ..... 470

Interactive dynamics between rhizosphere bacterial and viral communities facilitate soybean fitness to cadmium stress revealed by time-series metagenomics .....471

Soil virome dynamics and ecological regulation during revegetation of rare earth tailings .....472

Impact of Warming and Fertilization on Viral Communities in Agricultural Soils ..... 473

How do soil viruses exert impacts on the soil carbon cycle under anaerobic? The ubiquitous but neglected part ..... 474

Rhizosphere phage–host interactions drive crop rotation-enhanced disease suppressiveness ..... 475

## Session 203002: Roles of Extracellular Polymeric Substances in Biogeochemical Cycling and Soil Health ..... 476

Extracellular polymeric substances in soil: drivers, functionality and future research directions ..... 476

Small fractions, large effects: the role of extracellular polymeric substances in soil function ..... 477

Seeing the Invisible: Visualizing Enzymatic Processes in Soil Hotspots ..... 478

Increased microbial extracellular polymeric substances as a key factor in deep soil organic carbon accumulation ..... 479

Characterization of compound-specific extracellular polysaccharide biomarkers across soil organisms and plants ..... 480

Regulatory effects of Mortierella on soil microbial network stability and aggregate structure under saline-alkali stress ..... 481

Functional Group Composition and Persistence of Extracellular Polymeric Substances in Soils ..... 482

Modeling the Turnover and Stabilization of Soil Extracellular Polymeric Substances (EPS) ..... 483

Microbial extracellular residues dominate long-term soil organic carbon storage ..... 484

Investigating Microbial Intracellular and Extracellular Carbon Production Efficiency Using 13C and 18O Isotope Techniques ..... 485

Mineral-EPS Interface Coupling Process: Contribution of Maillard Reaction-Driven Geological Polymerization to Carbon and Nitrogen Fixation ..... 486

Pore-scale spatial heterogeneity of moisture and microbe interactions during moisture evaporation ..... 487

Plant growth-promotion triggered by poly-γ-glutamic acid is associated with facilitation of bacterial cross-feeding networks of the rhizosphere ..... 488

Nitrogen deposition reorganizes extracellular polymeric substances production through microbial physiological adjustments in subtropical forest soils ..... 489

Mechanisms of simulated warming and altered precipitation on microbial metabolism residues in soils of abandoned land ..... 490

Microbial Legacy: The Differential Transformation of Biomass Components into Soil Organic Matter ..... 491

Effect of Humic acid on lysozyme interaction with montmorillonite and kaolinite ..... 492

**Session 203003: Soil Biodiversity and Soil Health: Interactions, Indicators, and Innovative Approaches ..... 493**

Biochar effects on soil physicochemical properties and biological activity in Mediterranean agricultural soils ..... 493

Evaluating tillage effects on soil biodiversity across functional groups using extracellular eDNA ..... 494

Long-Term Effects of Nitrogen and Lime Application on Plant–Microbial Interactions and Soil Carbon Stability in a Semi-Arid Grassland ..... 495

Linking Soil Food Web Stoichiometry to Ecosystem Function and Soil Health ..... 496

Enzyme-Mediated Nutrient Dynamics in Cover Crop Systems: Temporal and Spatial Optimization Strategies ..... 497

Steering soil microbiomes for healthier crops ..... 498

Rewiring Micro-Food Webs: How Copper Nanopesticides Can Reshape Nitrogen Fluxes via Trophic Decoupling ..... 499

Contrasting global patterns and drivers of soil bacterial and fungal diversity responses to crop rotation ..... 500

The effect of iron-bound organic carbon on fungal denitrification in regulating upland red soils $N_2O$ emission ..... 501

Unraveling soil microbial guilds driving phosphorus, nitrogen, and carbon transformations through multi-omics approaches ..... 502

Multi-scale Biochar-hydrogel for Enhanced Soil Health and Crop Production ..... 503

Interactive Effects of Compost, Clay, and Plant Presence on Soil Aggregate Fractions and Biochemical Properties in Sandy Soil ..... 504

Synergistic Effects of Clay, Hay residue, and Fertilizer in Sandy Soil ..... 505

Impacts of sample storage conditions on extracellular DNA-based assessments of soil biodiversity ..... 506

A data-driven methodology to identify key biological indicators linked with ecosystem services in agricultural soils ..... 507

Biochar-Compost Interactions: Impacts on Soil Health and Plant Performance in Regenerative Organic Systems ..... 508

Soil Enzyme Activities and Microbial Biomass Biomarker Associated with the Integration of Cereal Rye to Improve Tomato Soil-Borne Disease Suppression and Yield ..... 509

Soil Health Bioindicators: Sequences to Services across Europe for wide-scale monitoring ..... 510

A Next-Generation Approach to Soil Health in Brazil ..... 511

Soil organisms from multiple trophic levels regulate respiration in dryland purple soil ..... 512

Mycorrhizal fungal communities in Sarayaku territory: Impact of traditional agricultural practices ..... 513

Auxotrophic Bacteria in Maize Rhizosphere and Bulk Soil: Insights into Microbial Dependencies ..... 514

Soil management drives microbial diversity patterns and community structure under Cd and Cr contamination ..... 515

The role of microorganisms in changing the properties of eroded soils ..... 516

Harnessing Soil Cyanobacteria for Resilient Agriculture: Evidence from a 20-Year Mediterranean Orchard Trial ..... 517

Permanent vegetation cover as a strategy to enhance soil multifunctionality in perennial crops in the Mediterranean basin ..... 518

Phosphate-Solubilizing Bacteria Enhance Sugarcane Growth: High-Potential Candidates for Sustainable Biofertilizer Development ..... 519

Model-Driven Microbiome: Next-Gen Soil Bioremediation ..... 520

Belowground nutrient transfer between Scots pine and bilberry mediated by ectomycorrhizas ..... 521

Relations of Soil Microbe-Resource Stoichiometry Varied Across Soil Depth ..... 522

Variations in synergistic benefits among different intercropping systems: evidence from crop, soil and soil biota in agroecosystems ..... 523

Crop Coexistence Redefines Belowground Microbial Assembly Toward N-Cycling Archaea and Fungal Resource Networks ..... 524

Soil microbial community structure in reclaimed and unreclaimed post-mining areas ..... 525

Conservation Tillage Reduces Mycotoxin Contamination in Black_Soil Maize Systems ..... 526

Soil Ecological Shifts Following Land Use Conversion to Agriculture in Southern Ethiopia ..... 527

Effects of Crop Residue Management Strategies on Soil and Root Nematode Assemblages ..... 528

The effects of nutrient-loaded biochar on earthworms in boreal agricultural soils ..... 529

SOIL MICROBIAL BIOMASS AND COMMUNITY RESPONSE TO DIFFERENT PESTICIDES UNDER GREENHOUSE CONDITIONS ..... 530

Developing a Framework for Soil Microbial Indicators ..... 531

Effects of sustainable cropping systems on soil fauna and microbial biomass and aggregate structure ..... 532

Impact of long-term conservation agriculture on soil biota and inter-taxonomic interactions in Andisols, Japan ..... 533

Effects of five-year of conservation agriculture on soil chemistry and soil biological communities in Japan ..... 534

Effects of Acai Seed Biochar Amendment on Chemical and Biological Properties of Brazilian Soils ..... 535

Overlooked migration risk of resistomes in mining soil environments ..... 536

Temporal and Specific Effects of Micronutrient Addition on Soil Microbial Communities in Desert Steppe ..... 537

3D Structure of Ground-nesting Bee Burrows under Fertilization Treatments in Black Soil Areas: A Study Based on X-ray CT ..... 538

Ecological strategies govern fungal performance on soil carbon cycling in agroecosystems ..... 539

Effects of compost application on rhizosphere microbial communities of wheat grown in sandy soil under different tillage practices ..... 540

Dung-applied anthelmintic drug Moxidectin alters free-living soil nematode communities ..... 541

Soil Carbon Trend Index (SCTI): A Biochemical Tool for Predicting Carbon Dynamics in Agricultural Soils ..... 542

Assessment of the Stabilizing Effect of Compost and Phosphogypsum on the Metabolism of Bacillus subtilis and Pseudomonas putida in Sod-Podzolic Soil Contaminated with Lead and Zinc ..... 543

Locally Conserved Microbial Signatures as Global Indicators of Plant Productivity ..... 544

Predatory protists – crucial drivers of soil antibiotic resistance ..... 545

Soil Health Under Climate Change Era: Restoration Strategies using Nanobiotechnology and Soil Engineering ..... 546

Dynamics of Native Low Molecular Weight Organic Substances (LMWOS) and Their Relationship to Soil Quality Indices in Gray Lowland Soil ..... 547

Comparison of different methods for estimating microbial biomass in biochar-amended soils ..... 548

Species-Specific Effects of Earthworm on Soil Modification Functions Across an Ecosystem Development Gradient: Evidence from Miyakejima and Mikurajima, Japan ..... 549

The response of soil faunal and biological activities to silvicultural management in a Tuber Magnatum Pico productive area in Tuscany, Italy ..... 550

Optimizing Methods for Selective Removal of Soil Nematodes to Study Their Functional Roles: Toward Effective Techniques with Minimal Impact on Soil and Plants ..... 551

A Functional Molecular Framework for Scalable Soil Health Assessment ..... 552

Rhizosphere Compartmentation Reveals Conserved and Divergent $CO_2$ Responses Across Wheat Genetic Lineages ..... 553

The impact of veterinary antibiotics on the functional diversity of microorganisms in agro-sod-podzolic soil ..... 554

Effect of veterinary antibiotics on test plants and enzymes activity and microbiological respiration of sod-podzolic soil ..... 555

Disentangling plant community and environmental controls on soil-borne pathogens in grassland ecosystems ..... 556

Coupling of Intraspecific Root Traits and Rhizosphere Fungal Communities in Cynodon dactylon across Hydrological Gradients of a Reservoir Drawdown Zone ..... 557

From Soil to Shoots: Fungal Communities in Pea-Barley Intercropping ..... 558

Regulation of selenium uptake and translocation and hyphal contribution rate in soybean by co-inoculation with AMF and Rhizobium ..... 559

Driving Mechanisms of Antibiotic Resistance Genes in Urban Forest Soils ..... 560

Urbanization-driven forest soil greenhouse gas emissions: Insights from the role of soil bacteria in carbon and nitrogen cycling using a metagenomic approach ..... 561

Can soil protists improve plant growth? ..... 562

## Session 203004: Soil Biogeochemistry in Wetlands: Foundations for Restoration and Climate Resilience ..... 563

From Global Carbon Store to Climate Feedback: 25 Years of the Enzymic Latch in Wetlands ..... 563

Nonlinear response of anaerobic methane oxidation to water table drawdown in peatlands under climate warming ..... 564

Exploiting Soil Recalcitrant Phosphorus (P) Drives Invasion: Adaptive P-acquisition Strategies of Spartina alterniflora in Chinese Coast ..... 565

Millimeter-scale niche differentiation of N-cycling microorganisms across the soil-water interface has implications for $N_2O$ emissions from wetlands ..... 566

Climate warming suppresses the preservation of metal-associated organic carbon in peatlands ..... 567

Nitrogen input regulates soil carbon fixation via microbial-driven mineral-associated organic carbon formation in wetlands ..... 568

Thiol-activated ROS generation by particulate organic matter: The overlooked role of interface-accelerated organic radical chain reaction ..... 569

Water level regulation for reducing carbon emissions in urban restored wetlands ..... 570

Planting density constrains soil organic carbon pools during native plant restoration following Spartina alterniflora removal across invasion chronosequences ..... 571

Impact of Phenolic Additions on Microbial Properties of Peatland ..... 572

Soil structure determines dissolved organic carbon release from peat soils ..... 573

Microbially Mediated Mechanisms of PFAS-Induced Soil Carbon Priming Effects in Mangrove Ecosystems ..... 574

The Water Table Crux for Peatland Recovery ..... 575

Role of Iron Minerals in Carbon Stabilization in Redox-Active Ecosystems ..... 576

Iron Speciation as an Interpretive Framework for Pedochemical Variability in $CO_2$-Degassing Mofette Ecosystems ..... 577

Recovery of wetland soil function under passive and active hydrological restoration: evidence from multi-decadal spectral indicators ..... 578

Vertical Heterogeneity of Soil Arsenic Distribution and Its Relationship with Iron-Manganese Minerals Geochemical Barrier Combined with Microbial Effects ..... 579

Coupled effects of human activities and river–Lake interactions evolution alter sources and fate of sedimentary organic carbon in a typical river–Lake system ..... 580

Redox processes of particular organic matter in mediating carbon emissions in peatlands ..... 581

## Session 203005: Soil Microbiomes - Importance for Climate Resilient Future, Degraded Lands Restoration and Plant Health Control ..... 582

The application of liquid soil activator increased the activity of soil microbiota and enhanced the degradation of straw and plant growth in two different field locations ..... 582

Impacts of soil biostimulants on 'Valencia' sweet orange performance on Flatwoods and Ridge soils in Florida ..... 583

A Niche-Based Approach of Endemic Cyanobacteria in Soil and Water Conservation in Saline Soils ..... 584

A SWEET Challenge: Less Sugar for Rhizospheric Microbiome Under the Successive Wheat Rotation ..... 585

Shrub-Crop Microbiome and Mycorrhizae Hyphal Interactions: A Novel Rhizosphere Alliance to Mitigate Drought and Promote Beneficial Microorganisms in the Sahel ..... 586

Tradeoffs between microbial life-history strategies drive soil carbon cycling during revegetation in karst ecosystems: A metagenomic perspective ..... 587

Rice aluminum resistance facilitated by bacterial modification of root cell wall in acidic soil ..... 588

Methanotrophic activity as a driver of soil carbon cycling in agricultural soils ..... 589

Combined Microbial Inoculation and Reduced Inorganic Fertilization Enhances Diversity and Functionality in Potato Rhizosphere Microbiome at Field Scale ..... 590

Mycorrhiza Helper Streptomycetes Strains for Combating Phytophthora Blight ..... 591

Leguminous Cover Crops Enhance Soil Microbial Communities and Tea Quality via Rhizosphere Microbiome Modulation ..... 592

Global Change and Human Activity on Soil Microbial Community and Metabolism ..... 593

A Novel Strategy for Rapid Discovery of Disease-Suppressive Functional Microbial Consortia Using High-Throughput Microbial Community Synthesis ..... 594

Adaptive Responses of Soil $N_2O$-Reducing Bacteria to Fluctuating $O_2$ Levels ..... 595

Uncovering Potential Lanthanide-Dependent Enzymes in High-Rare-Earth Environments ..... 596

Beyond plant diversity: plant productivity responses to extreme drought are linked to arbuscular mycorrhizal fungal diversity ..... 597

Phosphogypsum Effects on Soil Microbial Communities Revealed by PLFA Analysis in Arenosol and Meadow Chernosem Soil ..... 598

Machine-Learning-Driven Decoding of Microbial Quinclorac Cometabolic Degradation ..... 599

The stem microbiome assists maize in resisting stalk rot ..... 600

Resistant crops engineer beneficial soil microbial legacies for disease suppression ..... 601

Long-term soil storage highlights the role of precipitation history in microbial dynamics and $CO_2$ emissions ..... 602

Culture-Dependent Bacteriome Analysis Reveals PGPB Candidates for Okra Biopriming under Salinity Stress ..... 603

Applying wild (NatCom) soil microbiomes to alleviate primary stressors for peas and wheat ..... 604

The diverse autotrophic communities of mangrove sediments ..... 605

Response mechanisms of plant-soil nutrients and microorganisms to N:Ca ratio in poplar plantations of Northeast China ..... 606

The impact of trees on soil microbial biomass and $CO_2$ emissions from fertilized soil .. 607

Reseeding Caragana korshinskii recovers soil microbiome structure but not stability or complexity after eight years in degraded desert steppe ..... 608

Unraveling the mechanisms of halotolerant plant growth-promoting microbes in saline–alkaline habitats through microbial diversity, functional traits and transcriptomics ..... 609

Tracing the dynamic life story of soil microbial hotspots ..... 610

The Regulatory Role of Rhizosphere Microorganisms in Tobacco Resistance to Black Shank Disease ..... 611

Easily biodegradable organic materials serve as soil biostimulants to rapidly enhance soil aggregate stability by increasing fungal biomass ..... 612

Comparison of Soil Microbial Community Structure in the rhizosphere of Diploid, Triploid and Tetraploid Watermelons ..... 613

Comparative Analysis of Soil Microbial Community Structures in Rhizosphere of Two Texture-Differentiated Lotus Root Varieties ..... 614

Effects of Different Fertilization Regimes on Aromatic Components and Root-associated Microbiota in Peppermint (Mentha piperita L.) ..... 615

Differences of soil microbial community structures in rhizosphere between gynoecious and monoecious cucumbers ..... 616

Ozonate Irrigation: Soil Microbial Stress, Nematode Suppression and Tomato Brown Rugose Fruit Virus control ..... 617

Unlocking Multifunctionality: The Interplay Between Legume-Cereal Intercropping, Soil Microbial Communities, and Ecosystem Cycles. ..... 618

Harnessing Halophyte Microbiomes to Build Wheat Resilience under Extreme Coastal Salinity ..... 619

Recovery Mechanism of Kobresia humilis in Alpine Meadows ..... 620

Establishing Genetic, Phylogenetic and Functional Mechanisms that Shape Acidobacteriota Diversity of Arctic Tundra and Boreal Forest Soils ..... 621

Impact of multiple driving factors on soil bacterial community dynamics in a wheat-maize/soybean rotation system in the North China ..... 622

Microbial Hydrogen Cycling as a Potential Driver of Drought Resistance in Agricultural Soils ..... 623

Fungal mutualism in plant growth: dark septate endophytes and arbuscular mycorrhizal colonization in soybean (Glycine max) ..... 624

Synergistic Soil Remediation and Microbial Network Reconstruction: Leguminous Cover Crops and Probiotics in Degraded Dry-Hot Valley Coffee Plantations ..... 625

Integrated impacts of land use intensification on greenhouse gas emissions and soil microbial communities in the Taihu Lake Region: patterns, mechanisms, and implications ..... 626

Soil microbial communities regulate plant response to drought stress ..... 627

Assessing the Role of Soil Amendments and Root-Associated Fungi in Anaerobic Soil Disinfestation ..... 628

Fungal community shifts govern microbial carbon use efficiency across an elevation gradient at Qinling mountain, China ..... 629

Microbial Drivers of High Fertility in Black Soil: A Metagenomic Perspective on Enhanced Nutrient Cycling and Metabolic Resilience ..... 630

Effect of biological nitrification inhibition on the rhizosphere microbiome of maize .... 631

Sustainable Alternatives to Peat-Based Growing Media: Microbial Functionality as a Key Indicator ..... 632

Effects of inter-row management and cover crops on vineyard rhizosphere microbial communities ..... 633

What fungi can we count on in the mitigation of climate change influence on forests in different climatic regions – comparison of arbuscular and ectomycorrhizal solutions in Serbia and China ..... 634

Soil Bacterial Succession as a Driver of Rhizosphere Function: Wheat-Derived Plant Growth-Promoting Rhizobacteria and Plant Stress Resilience ..... 635

Contrasting patterns of belowground biodiversity homogenization across urban greenspaces ..... 636

**Session 203007: Diversity Dynamics and Ecosystem Functions in Soil Microbial Ecology ..... 637**

Life and death of ammonia oxidizers drives soil organic carbon accumulation in long-term different fertilization soils ..... 637

Does land use conversion from temperate steppe to farmland increase broad scale homogeneity of soil biota and its functional genes? ..... 638

Challenges and opportunities in interpreting the complex microbial interactions in soil 639

Experimental drought drives divergent succession of soil microbiota ..... 640

Bacterial cheating is a widespread resource acquisition strategy in soils ..... 641

Analysis of Soil Microbial Community Composition and Diversity Under Different Forest-Medicinal Plant Intercropping Patterns ..... 642

Wetland Age and Seasonality Drive the Succession of Active Methanotrophs in Constructed Wetlands ..... 643

Leveraging the root economics space: outsourcing rice varieties outperform do-it-self strategies under stress ..... 644

Carbon monoxide metabolism as a driver of volcanic soil colonisation ..... 645

Eco-evolutionary patterns of microbial engine that drives reduction of greenhouse gas 647

The impact of microbial-mediated crop residues and their humification products on soil organic matter transformation ..... 648

Regulation of methane oxidation in natural grassland by animal urine addition gradients ..... 649

Effects of Different Straw Return Methods on Soil Microbial Community Structure and Diversity ..... 650

Tropical rubber plantations' expansion alters multiple ecosystem functions and C storage ..... 651

Cobamide Auxotrophy and Unexpected Cobamide Synthesis Potential in Organohalide-respiring Dehalococcoidia ..... 652

Crop rotation and residue management enhance banana health by enrichingcore antagonistic microbes ..... 653

Effects of Perennial and Annual Plant Life Forms on Rhizosphere Bacterial Communities in Saline–Alkali Desert Soils ..... 654

Repeated Drying-Rewetting Cycles Maintain Core Soil Microbiota Stability While Driving Metabolic Decline and Network Evolution ..... 655

Widespread presence of extraordinary high-affinity of atmospheric methane oxidation by conventional methanotrophs in paddy soils across China ..... 656

Decoding Deep Soil Microbial Response Dynamics to Afforestation in Semiarid Regions: Biotic-Abiotic Trade-offs Under Land-Use Transition ..... 657

Microbial growth is the key to soil organic carbon cycling ..... 658

Elucidating Soil Microbial Community Activity Through Sipros-and-Aerith-Assisted Proteomic and Metabolomic Stable Isotope Probing ..... 659

Microbial interactions drive microbial succession during soil formation ..... 660

Soil Bacterial Diversity at the Molecular Level: Origins, Consequences, and Implications ..... 661

Synergistic remediation of desertification and carbon sequestration in extreme environments via region-tailored acclimated microbial-biochar systems ..... 662

Microbial CHON Assimilation and Stoichiometric Strategies in Natural and Agricultural Black Soils Revealed by Multi-Isotope Tracing ..... 663

Multi-stressor environments reshape soil microbial biodiversity and genomic strategies, favoring stress-adapted and unknown taxa ..... 664

Summer drought impacts micropredator abundance and microbial foodweb structure in a rewetted fen peatland ..... 665

Effects of Disturbance Intensity on Soil Microbial Diversity, Composition, and Network Complexity in Coastal Georgia, USA ..... 666

The Effect of Nitrogen Enrichment on Soil Fungal and Bacterial Community Assembly Processes and Phylogenetic Diversity in Wetland ..... 667

# 204 Soil Mineralogy ..... 668

## Session 204003: Disciplinary Development and Interdisciplinary Frontiers in Soil Mineralogy ..... 668

Clays as Therapeutic Agents: A Focus on Mineralogy and Geochemistry of Geophagic Clays at Mfensi-Adankwame in the Ashanti Region of Ghana and their Healing Properties ..... 668

The mineralogical mechanisms of solid phase aluminum mobilization during soil acidification ..... 669

Quantifying the direct and indirect effects of soil-forming factors on clay mineral abundance ..... 670

Models of rock weathering in soil environments based on rock fractal geometry ..... 671

Clay mineralogy of soils from cold environments of Siberia, Russia ..... 672

Contributions to the Study of Geophagic Clays in Africa ..... 673

Mineralogical and Geochemical Contributions to the Study of Clays and Clay Minerals in Africa ..... 674

Elucidation of Chemical Structure of Soil Clay Minerals Using Electron Probe Microanalyzer ..... 675

Crystallinity–solubility relationship of phytoliths derived from different gramineous plants: validation using X-ray diffraction analysis ..... 676

Mineralogical Composition of Bulk and Clay Fractions in Mongolian Soils: Insights from X-Ray Diffraction Across Arid to Forest-Steppe Gradients ..... 677

# 206 Hydropedology ..... 678

## Session 206001: Hydropedology: Addressing Real-World Problems Through Interdisciplinary Science ..... 678

A Novel Rainfall-Based Model for Forecasting Soil Moisture Content ..... 678

Modeling the spatiotemporal changes in soil moisture under different vegetation types in the farming-pastoral ecotone of northern China ..... 679

Soil aggregate stability along a gradient of flooding intensity in the riparian zone: the role of root functional traits ..... 680

Evapotranspiration varies across different landscape units, influenced by hillslope position, soil properties and vegetation: An example from the Qinghai-Tibet Plateau ... 681

Identifying spatiotemporal patterns of hillslope subsurface flow in an alpine critical zone on the Qinghai–Tibetan Plateau based on three-year, high-resolution field observations ..... 682

Biochar-Induced Changes on Soil Nutrient Retention and Saturated Hydraulic Conductivity of Sandy Loam Soil in Lahar-laden Area of Zambales, Philippines ..... 684

Addressing water security in DOCG vineyards: a hydropedological framework linking soil water balance, plant stress, and berry quality ..... 685

Runoff and Sediment Response to Rainfall and Vegetation Cover in the Toutun River Basin（Xinjiang,China） ..... 686

Spatiotemporal variations and driving factors of groundwater ecosystem service value in a typical arid region:A case study of the Xinjiang, China ..... 687

Non-monotonic Snow Cover Control on Frozen-Soil Hydrothermal Regimes and Spring-drought Propagation in a Warming Semi-arid Forest Steppe ..... 688

Irreversible soil carbon and nitrogen loss during the thermokarst lake succession under climate change in the Tibetan Plateau ..... 689

Deciphering Soil Water-Carbon Coupling in the Earth’s Critical Zone and Its Environmental and Edaphic Controls ..... 690

Paddy cultivation history affects soil water dynamics and water balance by altering soil physical and hydraulic parameters ..... 691

Modelling water retention curves for hydrophobic granular soils ..... 692

Coupling relationships and threshold effects between vegetation cover and soil moisture across eco-geographical zones on the Loess Plateau. ..... 693

Divergent ecohydrological adaptation mechanisms of restored vegetation driven by micro-topography: Structural decoupling, hydro-thermal trade-offs, and competitive depletion ..... 694

Process-Oriented Watershed Delineation in Human-Modified Plain Farmlands: Key Constraints and Recent Advances ..... 695

Redistribution of hydrological and dissolved nutrient by self-organized shrubs: strategies to collect rain and nutrient for surviving in drylands ..... 696

Pore Architecture, Water Dynamics, and Climate Sensitivity of Mountain Volcanic Soils: Integrating SEM–DIA and NMR Relaxometry for Hydropedological Assessment ..... 697

Infiltration-Runoff Processes in Soil-Epikarst Systems on Karst Hillslope in Southwest China ..... 698

An Eco-Friendly Dual-Tracer Method Combining Synthetic DNA Fragments and Heat for High-Resolution Characterization of Aquifer Hydraulic Conductivity ..... 699

Interactions between pollutants, antibiotic resistance and pathogens during transition from untreated to treated wastewater irrigation: a multiscale approach ..... 700

Development of Environmental Benchmark of Cr(VI) in Soils for the Protection of Groundwater Quality ..... 701

Quantitative Characterization and Prediction Model for the Evolution of Soil Cracks in the Daqing Region ..... 702

A Hybrid SWAT-LSTM Framework for Daily Sediment Load Prediction in the Data-Scarce Songhua River Basin, Northeast China ..... 703

A physics-guided representation embedding framework for transferable estimation of soil water content and bulk density in Mollisols using TDR ..... 704

# 207 International Soil Modeling Consortium ..... 705

## Session 207001: Modelling Soil Processes from Ped to Global Scale ..... 705

Probabilistic and Entropy Models of Soil Properties for Contemporary Processes Assessment ..... 705

Advancing Daisy's denitrification function to improve predictions of nitrous oxide emissions from agricultural soils ..... 706

The impact of agricultural land use on soil hydraulic properties and hydrological functioning across the lowlands of England and Wales ..... 707

Differentiable Hybrid Modeling for Data-Driven Discovery of Hidden Processes in Soil Water Retention ..... 708

Modeling On-Farm Spatial Variability of Crop Yield ..... 709

Coupling soil biogeochemical processes and structural dynamics in a pore-scale model for an advanced understanding of organic carbon and nitrogen turnover ..... 710

Fusing ERA5-Land and SMAP L4 for an Improved Global Soil Moisture Product ..... 711

Quantitative Analysis of Pore Scale Factors Effecting Permeability in Porous Media ... 712

Improving Digital Soil Hydraulic Characterization: A Workflow for Enforcing Periodic Boundary Conditions on Tomographic Soil 3D Images ..... 713

Multi-scale simulations of soil transport properties with dynamic soil structure: combination of molecular, micro and continuum approaches ..... 714

A New Nonlinear Method for Simulating Nitrogen Pollutant Transport in Farmland .... 715

Predicting the Impacts of Metal Nanoparticles on Soil Properties: A Machine-Learning–Based Study of Soil Health Dynamics ..... 716

Simulating Soil-Plant-Climate Interactions and Greenhouse Gas Exchange in Boreal Grasslands Using the DNDC Model ..... 717

Process-based modelling of river sediment composition incorporating pedogenetic processes at the catchment scale: the Sendaigawa River basin, Japan ..... 718

Evaluating Conditioned Probabilistic Subsampling for the Validation of 3D Regional Subsurface Models using Legacy Data ..... 719

Generalizability optimization of soil thermal conductivity models: unified estimation of dry- and saturated-soil thermal conductivity ..... 720

SoilData: A MapBiomas Initiative for Soil Data Rescue, Curation, and Open Science in Brazil ..... 721

Estimation of Soil Temperature at Depth Using Time Series of Satellite Imagery ..... 722

Predicting soil and macropore hydraulic properties: combination of direct simulations and machine learning ..... 723

The Hidden Oxygen Sink: Carbon Dynamics in Closed Systems ..... 724

A spatially explicit model for watershed nitrogen fate through multi-scale integration of soil biogeochemistry and hydrology ..... 725

Fusion simulations based on process-based modeling and AI-technology for groundwater storage and quality in the Mollisol Regions ..... 726

Assessing Future Climate Change Impacts on Soil Erosion, Agricultural Nonpoint Source Pollution, and Crop Growth in the Huai River Basin ..... 727

MapBiomas Soil: Soil Information across Four Decades of Land Use and Land Cover Change ..... 728

Towards predicting plant uptake of trace elements with a mechanistic mass-balance model ..... 729

## Session 207002: Soil Erosion Modelling: Global Alliance ..... 730

The influence of the soil cover on the reliability of soil erosion modelling on the Central Russian Upland ..... 730

Spectra-based predictive mapping of soil erosion rates in sloping croplands ..... 731

InSAR-based Quantitative Remote Sensing of Spatiotemporal Characteristics of Soil Erosion ..... 732

Assessments of Gully Erosion Susceptibility in Typical Thick-Layer Mollisol Region of Northeast China ..... 733

Pasture Restoration Improves Runoff, Soil loss, and Sediment Sorting in a Brazilian Karst Basin ..... 734

Influences of slope gradient and length on runoff and soil erosion of arable farmland in Northeast China: A modeling approach with APSIM ..... 735

Impacts of Soil Erosion on Soil Organic Carbon Dynamics and Carbon Neutrality ..... 736

Impacts of cascading check dams on sediment yield in the middle Yellow River Basin: Insights from 50 years of grid-cell-level simulation ..... 737

Mobilizing Legacy Data for Continental-Scale Erosion Modelling: The MapBiomas SoilData Initiative in Brazil ..... 738

# 301 Soil Evaluation and Land Use Planning ..... 739

## Session 301001: Better Management of Organic Agro-Waste in Response to Various Global Environmental Issues ..... 739

An Evaluation of the Quantity–Intensity Relationship of Potassium (K) on Some Lowland Rice-Growing Soils ..... 739

Reconciling carbon sequestration value and soil health benefit of organic amendments 740

Synergistic Microbial Consortia from the Black Soldier Fly Mediate Broad-Spectrum Suppression of Plant pathogens ..... 741

Current Situations of Antibiotic Resistance Genes in Compost, Soil, and Sediment in Vietnam ..... 742

$CO_2$ emission from forest soils in Western Japan as affected by water repellency ..... 743

Facultative heap compost effects on soil $N_2O$, $CO_2$, and $CH_4$ emissions under aerobic incubation ..... 744

$^{15}N$ tracing reveals nitrogen uptake dynamics and retention under contrasting irrigation and residue management in paddy soils ..... 745

Better agro-waste management for soil health ..... 746

Anaerobic fermentation of food waste to connect fork to farm and minimize greenhouse gas emissions ..... 747

Silicon Rich Biochar from Crop Residues Reduces Heavy Metals in Soil and Paddy Rice in Central Vietnam ..... 748

PFRD-Net: An Optimized U-Net Architecture for Robust Detection of Agricultural Plastic Film Residue in UAV Imagery ..... 749

Evaluating nutrient dynamics in marginal soils amended with biochar and torrefied biomass with Plant Root Simulator probe ..... 750

Effects of Application of Ferment Solution Produced from Discarded Vegetable Leaves on Soil Microbial Community and Celery Growth ..... 751

Study on Spatial Distribution Characteristics of Soil Organic Matter in Tea Gardens of Laoshan District, Qingdao Based on GIS and the Impact of Different Altitudes ..... 752

Effects of repeated application of horse dung manure on the accumulation of the elements in topsoil of paddy fields -A case of newly reclaimed paddy fields in Kyoto University Farm, Japan- ..... 753

Biotic and Abiotic Catalytic Strategies for Accelerated Humic Substance Formation .... 754

Global Potential Effects Analysis of Biochar on Crop Yields and Soil Quality ..... 755

Revalorization of spent coffee ground as peat alternative for soilless culture ..... 756

**Session 301002: Soil Evaluation and Land Use Planning for Sustaining Productivity ..... 757**

Integrated Assessment of Soil Water-Storing Function across Australia: A Multi-Dimensional Approach to Mapping Soil Security ..... 757

Study on the Suitability Evaluation and Spatial Zoning of Soil Fertility Enhancement Technologies for Different Cropland Types in Yuanmou County, Yunnan Province, China ..... 758

Preliminary Study on a Method for Evaluating the Basic Soil Fertility of Medium and Low-Yielding Land in Anhui Province Based on Natural Soil Properties ..... 759

An interactive land suitability tool for Queensland, Australia ..... 760

WRB-Harmonised Soil Mapping to Support Sustainable Land Use Planning in Mediterranean Regions ..... 761

Spatial heterogeneity and driving factors of five global arable land datasets in China under a ‘single cropland map’ framework ..... 762

Background concentration and range of potentially toxic elements in Lebanese soils for land suitability assessment ..... 763

Long-term soil multifunctionality under climate trajectories, land-use transitions, and management practices ..... 764

Relationships among cultivated land quality, crop yield and economic benefit based on a long-term field experiment with different fertilization and mulching treatments ..... 765

Interpretable machine learning models analyze the mechanism of nutrient evolution in red soils of Jiangxi under the dual drivers of climate and social economy ..... 766

Soil–Geochemical Controls of NDVI Seasonality in Steppe ecosystems of the Turano–Uyuk Intramontane Depression (Tuva, South Siberia) ..... 767

Soil multifunctionality assessment in Grenoble Alpes metropolis using the ..... 768

MUSE method for sustainable land use planning ..... 768

Assessing the Physico-Chemical Properties and Fertility Status of Selected South African Wetland Soils Using XRF, SEM, and Soil Fertility Index ..... 769

# 302 Soil and Water Conservation/Soil Erosion and Soil-Water Conservation ..... 770

## Session 302004: Rethinking the Planning of Soil and Water Management Under Climate Change ..... 770

Soil Under Stress: Climate Change, Water Dynamics and Agricultural Resilience in Finland ..... 770

Will supplemental fertigation benefit potato productions with a changing climate in Atlantic Canda? ..... 771

Effects of testing non-AI autonomous precision deficit irrigation scheduling onto potato and raspberry crops in Poland. ..... 772

Climate-change-induced Increase in Rain Erosivity in Germany ..... 773

Mapping Gully Erosion Across the European Union ..... 774

Can soil magnetism affect the soil response to the magnetized water? ..... 775

Theory and Demonstration of Smart Water and Soil Management Technologies for Black Soil Cropland ..... 776

Sustainability challenges of vegetation restoration on the Loess Plateau ..... 777

From Free-Draining to Flood-Forming: How Compaction and Slaking Generate Runoff in Sandy Soils Under Extreme Rainfall ..... 778

Cross scale assessment of agricultural conservation measures for future erosion, soil carbon and crop yield in the Yangtze River Basin ..... 779

## Session 302005: Soil Erosion and Conservation ..... 780

Paleo-landscape features and their role for soil erosion initiation ..... 780

Porous Biochar Produced from Rice Waste Inhibits Soil Loss ..... 781

Slope Aspect Affects Soil Quality and Its Response to Soil Erosion on Temperate Gentle Sloping Farmlands ..... 782

Biochar application ameliorates soil and water loss on the soil-mantled karst slopes: mechanisms and benefits ..... 783

A systematic identification of multi-scale relationship between sediment load and environmental factors in the Ten Tributaries region of the Yellow River Basin ..... 784

SOIL MANAGEMENT AND CONSERVATION FOR AGRICULTURAL SUSTAINABILITY IN MALI VILLAGES ..... 785

Decoding impacts of slope length on sheet erosion based on calculus method ..... 786

Setting tolerable soil loss and land management targets across New South Wales, Australia ..... 787

Predicting Current and Future Erosion Risk across NSW, Australia ..... 788

Slope Gradient Modulates Pathways of Soil Erosion-Induced Corn Yield Losses in Northeast China’s Black Soil Region ..... 789

Effects of the size of biodegradable superabsorbent polymers on interrill erosion ..... 790

A study on soil erodibility and the applicability of estimation methods in Robinia pseudoacacia L. mixed forests on the Loess Plateau, China ..... 791

Early detection of runoff erosion as gully prevention strategy in sandy tropical soils, Kananga, Democratic Republic of Congo (DRC) ..... 792

From regional to global tillage erosion mapping: challenges, solutions and a demonstration in Canada ..... 793

Development Characteristics and Influencing Factors of Gullies ..... 794

in Typical Region on the Qinghai-Xizang Plateau from 1970 to 2025 ..... 794

Comparative Erodibility of UK Soils Under Different Climate Change Scenarios ..... 795

Evaluation of Silt Socks and Wollastonite-Enhanced Socks in Sediment and Phosphorous Management ..... 796

Synergistic Effect of Coal Fly Ash and Polyacrylamide on Enhancing Sandy Soil's Resistance to Wind and Water Erosion ..... 797

Tillage erosion - the blind spot in soil conservation ..... 798

Global Soil Erosion Dynamics and Drivers ..... 799

Effects of Straw Mulch in Hillslope Longitudinal Furrows on Soil Physicochemical Properties and Erosion Resistance in the Black Soil Region of Northeast China ..... 800

Yield decline across soil types under progressive soil erosion: Basis for soil conservation criteria in the Sudan Savanna ..... 801

Study on Soil Erosion and the Spatiotemporal Distribution Characteristics of Erosion Factors in the Northeast Cinnamon Soil Region ..... 802

Mechanism of Surface Runoff Erosion Transport and Its Verification and Application . 803

Long slope erosion-deposition patterns under different tillage systems driven by multiple erosion forces in the Chinese Mollisol region ..... 804

Exploration of Multi-Scale Spatiotemporal Differentiation and Influencing Factors in Yuanmou County Based on SBAS-InSAR ..... 805

Effects of Different Land Use Types on Soil Multifunctionality and Their Driving Mechanisms in Karst Fragile Ecosystems ..... 806

Arbuscular mycorrhizal fungal community is vulnerable to mining activity but play key roles in runoff regulation in rare earth mining areas ..... 807

Measuring tillage and water erosion under different tillage systems in a commercial potato farm in Atlantic Canada ..... 808

Soil Erosion in the European Union: A major threat for EU agriculture ..... 809

Drainage network connectivity controls phosphorus transport and export ..... 810

Integrating Multi-Scale Soil Evaluation and Ecosystem Service Assessment for Sustainable Land Use Planning with Targeted Agri-Environmental Measures ..... 811

A Half-Century Intensification of Lateral Carbon Transfer along the Congo Basin's Land–Ocean Aquatic Continuum ..... 812

Check dams as a major terrestrial sink for eroded sediment and organic carbon on the Chinese Loess Plateau ..... 813

Research on key algorithms for global erosion topographic factor extraction ..... 814

A topographic relief fitting mosaic method for eliminating seamlines of the SRTM and additional quasi-global DEM mosaics at 60°N latitude ..... 815

Long-Term Dynamics and Driving Mechanisms of Wind Erosion Across China (2001–2024) ..... 816

Mapping and Analysis of the Global Soil Erodibility Factor (K) ..... 817

Gully runoff is the primary factor triggering gravity erosion: A case study in the Top Ten Tributaries Watershed, China ..... 818

Differences in water erosion between intra-row and inter-row positions of maize in sloping farmland ..... 819

Hydromechanical Drivers at Raindrop Scale Underpin Soil Erosion Resistance Driven by Carbon ..... 820

Regional Soil Erosion Survey and Mapping in the Pre-GIS Era : Research Progress, Scientific Contributions, and Contemporary Implications ..... 821

Study on the Hydrodynamic Threshold of Soil Erosion Regulated by Vegetation on the Hilly-Gully Complex Slopes of the Loess Plateau ..... 822

Coupled Wind-Rain Forcing Alters Runoff Generation and Soil Loss Dynamics Across Soil Surface Conditions ..... 823

The response mechanism of organic carbon loss on loess slopes to the process of soil erosion ..... 824

Interactive Effects of Vegetation Configuration and Rainfall Characteristics on Runoff and Sediment Yield in the Ridge-Gully Slope System of the Loess Hilly-Gully Region ..... 825

A Framework for Global Soil Erosion Mapping（GSERmap） ..... 826

Improving Global Rainfall Erosivity by Using Regional Achievements ..... 827

Global-Scale Mapping of the Non-Agricultural Cover-Management Factor (Cnon-crop) for Soil Erosion Modelling ..... 828

Temporal Dynamics and Mechanism Evolution of Biochar in Regulating Erosion ..... 829

Processes in China's Loess Plateau ..... 829

Tracing soil redistribution rates following deforestation in Northern Hardwood Forests using $^{239+240}$Pu isotopes ..... 830

A Novel High-Resolution DEM Synthesis Method for Terraced Watersheds in the Loess Plateau ..... 831

Effects of crop type on the soil anti-scourability index of sloping farmland in the black soil region of northeast China ..... 832

Effects of Green Manure Incorporation and Tillage Practices on Soil Carbon Fractions and Soil and Water Losses in Sloping Red Soils ..... 833

A Methodological Framework for Large-Scale Gully Erosion Assessment: Insights from Contrasting Landscapes of China ..... 834

Regional-Scale Variability and Environmental Drivers of Soil Erodibility factor (K) in the NW Italian Alps ..... 835

Influence of grazing on soil structure of the Patagonian wetlands meadows (Vegas) ..... 836

Spatial Distribution and Erosional Significance of Hollows in Agricultural Landscapes of the European Russia ..... 837

Influence of Soil Cover Properties on Shallow Landslides: insights from a Pilot Basin in Southern Italy ..... 838

Effects of irrigation timing on early growth of Haloxylon ammodendron seedlings in southern Tajikistan ..... 839

Practical-measures investigation to achieve global soil erosion map by using sampling method ..... 840

Weakened role of check dams in reducing erosion-induced soil organic carbon transport in the Middle Yellow River Basin due to vegetation restoration ..... 841

The efficacy of hedgerow-grass ditch systems in controlling N and P losses in citrus orchards under variable natural rainfall events ..... 842

Soil and Water Conservation Planning by Estimating Complex Soil Properties from Easily Measurable Soil Properties ..... 843

Simulation of Wind Erosion under the Influence of Topography in a Temperate Grassland Landscape ..... 844

Effects of grass structure on wind erosion using a wind tunnel simulation ..... 845

From Aerosols to Soils: A Novel Pedological Framework for Identifying Aeolian Dust Hotspots in Dried Saline Lakebeds ..... 846

Modeling runoff and soil erosion amounts affected by slope gradient and length in black soil slope farmland of Northeast China based on APSIM ..... 847

Hydrologic regime determines catchment-scale dissolved carbon export patterns ..... 848

Dynamics of Soil Carbon and Nitrogen in Check-Dam Sediments: Impacts of Burial Time and Decadal Exposure Following Dam Breaching ..... 849

Field Evaluation of Vegetation with Contrasting Root Traits for Runoff and Soil Erosion Control on Sloping Agricultural Land ..... 850

Variability of hydraulic characteristics of sediment-laden rill flow under various slopes, water flows and sediment loads ..... 851

Effects of Crop Association on Soil Extracellular Enzyme Stoichiometry in Erosion-Prone Sloping Farmlands in the Rocky Mountainous Region of North China ..... 852

Influence of land use change and increased rainstorm on shallow landslide sediment connectivity in a small watershed of the Chinese Loess Plateau based on remote sensing ..... 853

Soil-root shear strength of gullies covered by different vegetation types on the Loess Plateau of China ..... 854

Response of soil erosion resistance to incorporated straw affected by different microbial inoculants in the black soil region of Northeast China ..... 855

Spatial variation of soil erosion resistance impacted by ephemeral gully on long gentle sloping cropland in the Mollisol region of China ..... 856

Morphological Development and Hydraulic Characteristics of Plunge Pools in the Gully Beds of Dry Red Soil in Yuanmou Dry-hot Valley ..... 857

Green-Ampt infiltration model calibration on a Peruvian Andean hillslope under different land uses ..... 858

Study on the dynamic changes in soil erosion and the stability of the soil organic carbon pool in the surface layer of purple soil on the slopes implemented the Grain-for-Green project ..... 859

A Dynamic Gully Erosion Risk Assessment Framework Considering Rainfall Regime Shift in the Songnen Typical Black Soil Region ..... 860

Effects of Farmland Shelterbelt Distribution on Wind-Water Compound Erosion in the Northeast Black Soil Region of China ..... 861

## Session 302007: Soil-Water Interactions: From Saturation to Repellency, From Processes to Management ..... 862

Changes in soil aggregates, pore characteristics, and their relationships with soil erodibility in periodically submerged soils. A case of the Water Level Fluctuation Zone in the Three Gorges Reservoir, China ..... 862

Technical Feasibility of Biomass Buffer Strips for Capturing Excess Nutrients from Agricultural Runoff ..... 863

Management-Induced Changes in SOM Composition Control Soil Wettability and Hydrological Function ..... 864

From Soil Morphology to Depression Hydrology: Diagnostic Criteria and Predictive Patterns in the Oka-Don Lowland ..... 865

Sensor-Based Modeling of Soil-Water Dynamics for Irrigation and Subsurface Hydrology ..... 866

Leveraging Multi-Temporal Environmental Data in a Long Short-Term Memory Model for Groundwater Nitrate Prediction ..... 867

Leptosols of Subarctic barrier islands: land – sea interface ..... 868

A challenging prediction: The heterogeneous nature of preferential flow masked by homogeneous moisture sensor responses ..... 869

Tree parasitism as a microclimatic amplifier: implications of Viscum album infection for soil moisture and repellency dynamics ..... 870

Salinity-Tile Drainage Linkages and their Impacts on Soil Health in the Red River Valley (United States) ..... 871

The influence of selected factors on the various phosphorus compounds in soils with a bog iron ore horizon ..... 872

Occurrence and assessment of water repellency in biochar and biochar-amended soils ..... 873

Characteristics, Driving Mechanisms, and Machine Learning Modeling of Nitrogen Runoff Losses from Chinese Rice Cropping Systems ..... 874

Machine Learning–Based Modeling of Phosphorus Runoff Losses and Their Component Fractions in Chinese Rice Cropping Systems ..... 875

Influence of Soil Microstructure on Capillary Rise in Disturbed and Undisturbed Sandy Arid Soils, Oman ..... 876

Tracing Water Use Sources in Rubber Monoculture and Rubber-Alpinia Oxyphylla Agroforestry Systems Using Hydrogen and Oxygen Isotopes ..... 877

Effect of dynamic salt precipitation on water and heat transport in unsaturated saline soil: Experiments and simulations ..... 878

Optimizing and Validating a Correction Formula for Xylem Water Deuterium Offsets in Field-Grown Apple Trees ..... 879

Transport Pathways of Nitrate in Stormwater Runoff Inferred from High-frequency Sampling and Stable Water Isotopes ..... 880

# 303 Soil Fertility and Plant Nutrition/Soil-Plant Nutrition/Soil Fertility and Fertilizer ..... 881

## Session 303001: Advances in Soil Fertility Management Through the Utilization of Organic Waste ..... 881

Integrated NP Management for Sustainable Soil Fertility and Crop Productivity ..... 881

Enhancing Wheat Drought Resilience through Organic Amendments: Integrating Soil Health Improvement and Antioxidant Defense Activation ..... 882

Degradation of Sugar Beet Pulp by Klebsiella sp. HDJT1 and Pseudomonas sp. C27: A Metabolic Cross-Feeding Strategy for Soil Health Improvement ..... 883

Optimizing nutrient balance in livestock waste to enhance soil organic fertilization and reduce environmental losses ..... 884

Nutrient Management Effects on Sustainable Yield, Soil Fertility, and Carbon Stock in a Cauliflower–Capsicum Cropping Sequence of the Northwestern Himalayan Region .... 885

Conservation Agriculture Impacts Soil Organic Carbon Sequestration, GHG reduction and Sustainable Crop Production ..... 886

Short-term interaction between earthworms, compost and biochar on GHG emissions and N mineralization ..... 887

Bacillus megaterium (S2-4a1) Improves Compost Biofertilizers by Solubilizing Potassium from Feldspar ..... 888

Innovative Nutrient Recycling through Black Soldier Fly (Hermetia illucens) Rearing: Comparison of three Organic Waste Substrates—Food Waste, Bread, and their Mixture. ..... 889

Clay-stabilised Composts to Enhance Soil Health and Carbon Storage in Sandy Soils. . 890

Straw return facilitates the availability of soil nitrogen by altering the metabolic distribution and nitrogen cycling processes ..... 891

Effects of straw incorporation on soil carbon and nitrogen sequestration in fallow and continuous maize cropping systems in Northeast China ..... 892

Differences in soil organic carbon accumulation caused by microbial-mediated tillage and carbon input ..... 893

Applying a combination of artificial humic acid and microbial agent to increase rhizosphere soil organic carbon content and maize yield ..... 894

Nutrients Leaching In a Maize Stover Biochar Amended Soil ..... 895

Organic management effect on soil characteristics: a comparison between vineyard and field crop rotation ..... 896

Organic Waste Amendments as Drivers of Soil Fertility and Microbial Activity in the Strawberry Rhizosphere ..... 897

Regulation of Aggregate Nutrients and Microbial Processes by Organic Materials Incorporation to Enhance Soil Quality and Crop Yield ..... 898

Soil Biogeochemical Responses to Composting and Organic Waste Application Across Agricultural Systems ..... 899

Partial organic substitution enhances ecosystem services in agricultural soils ..... 900

Optimizing management of organic inputs to improve biomass production and nitrogen efficiency in Danish organic cropping systems ..... 901

Torrefied biomass (biotorr) as soil amendment: insights from multivariate and temporal analysis ..... 902

Advancing Soil Fertility Management Using Tuna Meal Organic Waste: Impacts on Rhizosphere Microenvironment and Tea Quality ..... 903

Fractions of Phosphorus in Broiler Litter and its Fluxes in the Vadose Zone of a Transitioning Organic Farming System ..... 904

Agronomic and Environmental Effects of Straw Incorporation in the Rice–Wheat Rotation Region of the Yangtze River Delta: Research and Application Demonstration 905

The Influence of Organomineral Fertilizers and Biopreparations on Yield, Fruit Quality, and Soil Microbiological Properties under Golden Delicious Apple Orchards in Irrigated Light Chestnut Soils of Southeastern Kazakhstan ..... 906

Effects of Long-term Organic Fertilization in Tea Gardens on Soil Microbial Communities and Tea Quality ..... 907

The stability of softwood biochars and their impact on nitrogen retention in contrasting boreal soils over 14 years ..... 908

Effect of Biochar from Spent Media Growth on Kimchi Cabbage Cultivation in Upland Area ..... 909

Assessing the Agricultural Utilization Potential of Chicken Manure Biochar: Effects on Kimchi Cabbage Growth, Nitrogen Use Efficiency, and $N_2O$ Emissions in Upland Soil 910

Development of sisal seedlings with solid organic substrates, based on sisal residues, in Brazil ..... 911

Long-Term Effects of Organic Manure on Rice Productivity and Soil Nutrient in Paddy Systems ..... 912

Fermentation Characteristics of Sawdust-Bokashi and its Effect on Soil Fertility and Pepper (Capsicum spp.) Performance. ..... 913

Use of organic viticulture wastes as soil amendments to improve the function of clay soil in the Waipara region, New Zealand ..... 914

Nitrogen waste in cropping and livestock systems of Darusa village, Bangladesh ..... 915

Biogeochemical and Isotopic Responses on Soil Health Following Dairy Manure Compost Application in an Almond Orchard ..... 916

Effect of Pusa Decomposer-mediated rice residue management on soil phosphorus dynamics in a rice–wheat system of the Indo-Gangetic Plains ..... 917

Metagenomics reveals microbial regulation of soil nitrogen retention and supply under nitrogen fertilizer reduction with long-term residue retention ..... 918

Comparison of organic and inorganic amendments for conserving soil moisture and increasing crop yield in wheat under water limited conditions ..... 919

Study on the Effects of Different Organic Materials on Soil Humus and Nutrients ..... 920

Long-term field trials as a tool to evaluate the potential of compost to maintain grain yield and soil carbon persistence ..... 921

Synergistic Effects of Long-term Biochar Application on Soil Fertility, Microbial Biomass, and Rice Yield in Paddy Fields ..... 922

Partial Substitution of Chemical Nitrogen Fertilizer with Organic Fertilizer Enhances Rice Yield by Improving Soil Microbial Activity and Optimizing Soil Nitrogen Supply ..... 923

Decomposition characteristics of different organic materials and their effects on the carbon fractions of soil organic carbon in arable black soils ..... 924

The influence of organic materials on the chemical structure of humus in salt crust aggregates in the Yellow River Delta ..... 925

Short-Term Soil Fertility and Crop Yield Responses to Municipal Organic Waste ..... 926

Mechanisms of Biochar and Cattle Manure in Regulating the Microstructure of Humic Substances within Saline Fluvo-Aquic Soil Aggregates ..... 927

The influence of the application of sewage sludge compost on the yield of winter oilseed rape ..... 928

The soil rhizosphere metabolome's regulating mechanism on microbial communities depending on straw application depths ..... 929

Revitalizing Sandy Soils: Organo-Mineral Inputs Enhance Drought Resilience in Wheat and Microbes ..... 930

Optimizing Soil Fertilization Processes for Improving 4R Nutrient Stewardship ..... 931

Nutrient enriched biochar reduces chemical fertiliser requirements for forestry seedling growth ..... 932

Organic Waste Recycling in paddy:Enhancing Soil Health and Crop Quality - A case in Suzhou ..... 933

Different parts of corn plant residue returning to field caused the differences of humus composition in quantity and humic acid in molecular level in black soil ..... 934

Organic compounds in organically managed farmland in Fukushima and their effects on roots of A. thaliana ..... 935

Beyond Porosity: Dual-Mode Nitrogen Fertilizers from Metal-Modified Biochar ..... 936

Banana growers: Battling with soils for productivity in the Chitwan valley of Nepal ..... 937

In-Vessel Composting of Poultry Litter with Lignite Granules: A Strategy for Emission Mitigation ..... 938

Closing the Loop in Agriculture: Biochar for Soil Restoration and Productivity ..... 939

Biochar Utilization Strategies Based on Feedstock and Application Frequency: Effects of Wood and Chicken Manure Biochars on Crop Productivity ..... 940

Impacts of Applications of Three Wood Ash Types on Elemental Dynamics and Crop Growth ..... 941

From Waste to Resource: Stabilizing Nitrogen in Broiler Litter Using Granulated Lignite ..... 942

Regulation of Humification and Nitrogen Retention during Organic Waste Composting by Compound Microbial Agents ..... 943

Soil Nutrient Management in Oil Palm Plantation: The Application of Palm Oil ..... 944

Mill Effluent (POME) for Sustainable Agriculture ..... 944

FUNGAL CONSORTIUM ASSISTED COMPOSTING FOR RAPID STABILIZATION OF POULTRY LITTER ..... 945

Plant Available Nutrient Contributions from Steer Manure Compost in Semi-Arid Agricultural Systems ..... 946

Safeguarding global nitrogen sustainability by managing organic waste throughout the food supply chain ..... 947

The potential of organic waste recycling to replace mineral fertilizers in EU Member States ..... 948

Organic waste–derived soil amendments for climate-smart soil fertility management ... 949

The effects of different crop straw retention modes and nitrogen fertilizer rates on nitrogen runoff loss, crop yield and soil fertility in rice-wheat cropping systems ..... 950

Repurposing Lake Sediments as a Sustainable Phosphorus Source for Spring Barley: A Case Study in Denmark ..... 951

## Session 303002: Global and Regional Trends in Cropland Nutrient Balance and Use Efficiency ..... 952

Precision Nitrogen Management in Rice: Appraising Smartphone-Based Fertilizer Apps and Evaluating the Efficacy of Selected Nitrogen Management Strategies ..... 952

Effects of Annual Co-ordinated Phosphorus Fertilization under Wheat/Maize Rotation on Crop Phosphorus Uptake and Soil Phosphorus Content ..... 953

Organic Fertilizer Substitution Boosts Maize Yield in Upland Acidic Red Soils by Enhancing Soil Quality and Nutrient Availability: Insights from a 7-Year Study ..... 954

Evolution characteristics of soil phosphorus and its availability under long-term fertilization in black soil region, China ..... 955

Nutrient status and fertility constraints of highly weathered oil palm-growing soils in Thailand ..... 956

Fertilizer Use and Nutrient Management in Indian Agriculture ..... 957

The role of fertilizers for feeding the world ..... 958

Emerging soil nutrient limitations for global crop production ..... 959

Soil fertility and nutrient status of long-term durian orchards under organic–chemical management in Chanthaburi, Thailand ..... 960

Soil organic C composition and microbial community regulate soil enzymatic stoichiometry in Camellia oleifera land with cover crops ..... 961

Effects of Foliar Potassium Nitrate on Chlorophyll and Leaf Macronutrients in Sugarcane ..... 962

The Effect of Nutrient Management on Yield and Fruit Quality of Nam Hom Coconut in Thailand ..... 963

Cropland nutrient use efficiency: recent trends and targets for sustainable agriculture .. 964

Synergistic Effects of Mineral and Bio-organic Fertilizers Combined Application on Soil Multifunctionality and Yield and Quality of Coffee ..... 965

Calcium in Peanut Production: Towards Improved Nutrient Use Efficiency ..... 966

Organic Fertilizer Substitution Reshapes Carbon Component Distribution in Soil Aggregates Driving Niche Differentiation of Nitrogen Functional Microorganisms and Regulating Nitrogen Use Efficiency ..... 967

An organic nitrogen metabolite shapes soil–plant–microbe interactions and plant nitrogen acquisition ..... 968

A meta-analysis and monte carlo simulation of nitrogen management strategies on balancing yield and environmental impact ..... 969

Water and Nitrogen Management for Intercropping Systems Based on COMSOL Modelling: Crop Growth and Soil Environment ..... 970

Exploiting Iron-Efficient Groundnut Genotypes to Combat Iron Deficiency in Calcareous Soils ..... 971

Effects of gypsum application on rice growth and yield in paddy soils with varying heavy metal content ..... 972

Spatial distribution of medium and trace elements in tea garden soil of Laoshan District, Qingdao ..... 973

Effect of Manganese Foliar Application in Combination with Bacillus australimaris KU32 on the Stalk Elongation Growth Stage of Sugarcane Variety Khon Kaen 3 Planted in Calcareous Soil ..... 974

Nanoscale imaging reveals the kinetics of potassium release from biotite and its thermodynamic mechanism ..... 975

Balanced NPK Nutrition via TNAU-Water Soluble Fertilizer for Higher Yield and Nutrient Efficiency in Cotton ..... 976

Modelling the effect of soil nutrient and carbon mitigation measures in European agriculture ..... 977

Calibration and Validation of a Site-Specific Nutrient Expert Tool for Sorghum in the Sudano-Sahelian Region of Nigeria ..... 978

Paddy-Upland Rotation in Southern China's Red-Yellow Soils: A Meta-Analysis Reveals Short-Term Benefits and Long-Term Risks ..... 979

Vegetation types and management practices reshape mineral element cycling in tropical soil–plant systems ..... 980

Trends and geographic variation in adverse impacts of nitrogen use in Europe on human health, climate, and ecosystems: A review ..... 981

Potassium Management Strategies for Soybean–Corn Rotation Under No-Tillage in a Brazilian Oxisol ..... 982

## Session 303003: Global Phosphorus Stewardship: Innovations and Strategies for Sustainable Soil Systems and Food Security ..... 983

Simultaneous aerobic stabilisation of sewage sludge and chelator-assisted removal of toxic metals in a closed-loop process ..... 983

Blended Amendments to Reduce Soil Phosphorus Solubility and Mitigate Phosphorus Loss with Snowmelt Flooding ..... 984

Soil Phosphorus dynamics in a Vertosol with a long cropping history ..... 985

Fungal-mediated synergy between nitrogen fixation and phosphorus acquisition in a maize-lablab mixture ..... 986

Differential contributions of rare and abundant phosphate-solubilizing bacteria to organic phosphorus mineralization under long-term fertilization ..... 987

Scale-dependent limitation of the Mehlich-3 method for evaluating soil phosphorus across heterogeneous paddy soils in Japan ..... 988

Soybean-cotton rotation and soil phosphorus dynamics under long-term management and cover crops ..... 989

Phosphorus sorption in acidic soils following the application of Calciprill and sodium silicate ..... 990

Tracking of residual soil phosphorus pools using phosphate oxygen isotopes ..... 991

An insight on best management practices for phosphorus fertilization in cereal-based cropping systems ..... 992

Managing Legacy Phosphorus for Sustainable Soil Fertility ..... 993

Domestication of intercropping soil microorganisms: Legacies from a Long-Term Field Experiment ..... 994

Characterization and Dynamics of NaOH-Extractable Organic Phosphorus Species in Soils ..... 995

Acidic Phosphorus-Rich Biochars Promote the Gorwth of Okra in Coastal Salt-Affected Soil: The Critical Role of Phosphorus-Transforming Bacteria ..... 996

Improved recommendations for phosphate fertilizer application to promote soil health and reduce carbon emissions ..... 997

Sustainable Phosphorus Recovery Using Modified Olive Pomace Biochar ..... 998

Higher leaf phosphorus and nitrogen concentrations and greater allocation of phosphorus to lipids in Helicia and Heliciopsis than in other genera within the Proteaceae ..... 999

Phosphorus acquisition and pathogen defense: synergies versus trade-offs ..... 1000

Phosphorus Status and Management Implications for Sustainable Crop Production at the Institute for Agricultural Research Farm, Ahmadu Bello University, Zaria, Northern Nigeria ..... 1001

Biological Approach to Phosphorus Stewardship in Calcareous Soils ..... 1002

Endophytic fungi as a biotechnological approach to increase phosphorus use efficiency ..... 1003

## Session 303004: Novel Fertilizer Research and Industrial Development ..1004

Innovative Approaches to Sustainable Nutrient Management ..... 1004

Controlled-release fertilizer application:Coupling with an AI-designed maize system for more grain and lower emission ..... 1005

Carbon-Based Functional Fertilizers: Effective Strategies for Decreasing Antibiotics and Antibiotic Resistance Genes During the Aerobic Treatment Process of Livestock Manure and Controlling Their Spread in Soil-Cucumber Systems ..... 1006

Research on Creation and Application of Microbial Inoculants for Soil Conservation in Protected Tomato Production ..... 1007

Research Progress and application of Slow/Controlled-Release Fertilizers ..... 1008

Calibration of N, P, and K for Orange-Fleshed Sweet potato (Ipomoea batatas (L) Lam) Production in an Ultisol at Ikwo, Ebonyi State, Nigeria ..... 1009

Short-term effects of molasse-derived digestates from one- and two-stage anaerobic digestion on wheat crop and chosen soil properties ..... 1010

Optimization of ethyl cellulose-coated urea for high-performance controlled release .. 1011

INTEGRATED BIOFERTILIZER AND NPK APPLICATION ENHANCES SOIL QUALITY AND PRODUCTIVITY OF ONION AND WHEAT IN SEMI-ARID ENVIRONMENTS ..... 1012

Rhizobial Isolate YL 14 Biofertilizer Substitutes for Urea Fertilizer and Improves Yardlong Bean Growth and Nutrient Content ..... 1013

Development of carrier-based microbial inoculant and the assessment of soil application impact on Faba bean (Vicia faba) growth ..... 1014

Use of polyhalite as an ameliorant for sodic soils ..... 1015

Potassium availability but not movement from fertilizer bands is affected by the form of potassium, soil type, and co-application of phosphorus ..... 1016

Diatomaceous bio-silicon as a sustainable alternative to mineral silicon fertilizers: Impacts on rice yield, soilfertility, and heavy metal dynamics ..... 1017

Nanotechnology-based strategies for enhancing phosphorus and nitrogen delivery and utilization efficiency by crop species ..... 1018

Dissolution of Ca-Mg-K Based Mineral Fertilisers at the Immediate Soil Surface and Impacts on Soil Erodibility and Soil Surface Crusting ..... 1019

Potassium Precipitation Efficiency at Different Dilution Ratios in Thai Sugarcane Molasses ..... 1020

Nitrogen Release and Greenhouse Gas Emission From soils Treated with Biodegradable Polymer-Coated Urea Fertilizer ..... 1021

Chemical Gradients in the Fertosphere: Rethinking Fertiliser–Soil Interactions ..... 1022

Pure Water-Based Nano Pesticide-Fertilizer Co-delivery for Soil-Friendly Crop Nutrition and Protection ..... 1023

MOF-303 Reinforced Bio-based Coatings for Precision Nitrogen Release in Agriculture ..... 1024

Influence of a tailored composite amendment on soil health and wheat productivity in reclaimed tidal land ..... 1025

Microwave-assisted Synthesis of Multi-metal MOFs as Controlled-released Fertilizers ..... 1026

Effects of polyhalite placement on wheat seedling establishment using X-ray Computed Tomography ..... 1027

Synthesis of N-Zn Composite Synthetic Controlled Release Fertilizers ..... 1028

Potassium fertilisers in contrasting soils: solubility, speciation and potential plant availability of alternative and conventional formulations ..... 1029

Exudate pulses throughout the entire growth period trigger the increase in maize phosphorus use efficiency by modifying soil keystone microbial taxa ..... 1030

Unravelling the dissolution pathways and transformation of polyhalite fertilisers in contrasting soils through multi-scale imaging and elemental analysis ..... 1031

A Co-granulated Urea and Sulphur Fertilizer Reduces Soil $N_2O$ Emissions while Increasing Crop Yields ..... 1032

Comparison Evaluation of Nitrogen and Sulfur Release from Sulfur- and Polymer-Coated Controlled-Release Fertilizers ..... 1033

Field evaluation of dual-inhibitor urea in baby spinach on clay soil: implications for $NH_3$ and $N_2O$ mitigation in high-input horticulture ..... 1034

Improving Nitrogen Use Efficiency: Novel Enhanced Efficiency Urea Fertilisers. .....1035

Binary Polymer-Humic Soil Amendments as a Tool to Remediate Degraded Soils ..... 1036

The Synergistic Effect of Silicate and Calcium in Inhibiting Na+ Uptake: A Mechanism for Mitigating Salt Stress in Wheat .....1037

Technological Breakthroughs for Enhancing Nutrient Use Efficiency in Bio-based Coated Controlled-Release Fertilizers .....1038

Effects of Chlorella Application on Soil Quality and Crop Productivity in Saline–Alkali Soils of Xinjiang, China .....1039

Potential of Mg-Fe Layered Double Hydroxide as a Slow-Release Phosphorus Fertilizer Compared with Commercial Recycled Sources .....1040

Optimising Nitrogen Nutrition Index (NNI) for maize cultivation with controlled release fertilizer treatments guided by UAV remote sensing technology ..... 1041

Regulatory Effects of Soil Acidification Amendments Application on Enzyme Activity, Aggregates and Rice Yield in Red Soil .....1042

## Session 303005: Plant Nitrogen Utilization: From Cell to Field ..... 1043

Soil nitrogen deficiency and heat stress drive tissue-specific metabolic reprogramming governing nitrogen utilization in soybean ..... 1043

Enhancing Nitrogen Utilization and Profitable Corn Production While Minimizing Environmental Impact ..... 1044

Fertilizer-Driven Nitrate Availability and Waterlogging Resilience in Canola: Benefits and Micronutrient Trade-offs ..... 1045

Rapid induction of $NH_4^+$ efflux in rice roots under high-ammonium stress and its association with varietal differences in ammonium tolerance and ammonium-utilization efficiency ..... 1046

ISOPENTENYL TRANSFERASE3 activation triggers root ammonium hypersensitivity via the cytokinin ARR10/ARR12 CAP1 signaling pathway ..... 1047

The role of the nitrate transporter NRT1.1 in plant iron homeostasis and toxicity on ammonium ..... 1048

Regulation of the GS–GOGAT–GDH Pathway under Ammonium Nutrition: Mechanistic Insights into Nitrogen Assimilation and Utilisation Efficiency in Oil Palm Seedlings . 1049

Responses of Rice Production, $NH_3$ and $N_2O$ Losses to Biochar Application at Different Growth Season of Rice-Wheat Rotation ..... 1050

MGP1-mediated Mitochondrial ROS Homeostasis Couples Carbon Metabolic Switching with Nitrate Adaptation ..... 1051

Comparative Analysis of Arbuscular Mycorrhizal Fungi Characteristics in the Rhizosphere and Roots of Wheats with Different Ploidy Levels under Saline-Alkaline Soils ..... 1052

Phenolic BNIs drive shifts in nitrifying community structure and function leading to suppressed nitrification in an acidic soil ..... 1053

Phenolic acid methyl esters mitigate $N_2O$ emissions by inhibiting ammonia-oxidizing bacteria and stimulating $N_2O$ reducers in a moderately acidic soil ..... 1054

Direct Inhibition of Ammonia Monooxygenase by Biological Nitrification Inhibitor 1,9-decanediol Induces Energy Conservation and Stress Response in Nitrosomonas europaea ..... 1055

Rice promotes abundance of nitrogen fixing bacteria in paddy field soils ..... 1056

Effects of Biological Nitrification Inhibitors on Maize Yield and Nitrogen Utilization in Red Soil ..... 1057

Multivariate Analysis of Biomass Production and Nutritional Efficiency of Marandu Palisadegrass Fertilized with Bioinputs ..... 1058

Developing Machine Learning Protocol for Optimizing Nitrogen Nutrition in Rice .... 1059

Functional Complementarity in Cover Crop Mixtures Shapes Subsoil Carbon–Nitrogen Partitioning via Maize Reuse of Root Channel Legacies ..... 1060

Intercropping enhances soil nitrogen mineralization through C/N ratio-induced microbial network synergy ..... 1061

Short term impacts of biochar on vine tissues total carbon and nitrogen and their stable isotope compositions as well as berry yield in two vineyards in Southeast Queensland of subtropical Australia ..... 1062

Temporal dynamics of biological nitrification inhibition efficiency in wheat under varying degrees of plant growth realism ..... 1063

Hyperspectral imaging explains the leaf base to tip nitrogen spatial dynamics in maize ..... 1064

From methodological to mechanistic frameworks: assessing BNI efficiency by ..... 1065

integrating varying levels of plant growth realism ..... 1065

The contribution of N derived from deep-rooting cover crop mixture to soil N dynamics and subsequent maize nutrition ..... 1066

Variation Patterns and Influencing Factors of Fine Root Uptake of Different Nitrogen Forms with Stand Age in Cunninghamia lanceolata ..... 1067

Nitrogen-induced modulation of whole-plant transpiration under atmospheric drought ..... 1068

Nitrogen, manganese, iron and carbon resources acquisition are potential functions of wild rice Oryza rufipogon core rhizosphere microbiome ..... 1069

Developing an AI-based Precision Nitrogen Management Strategy for Corn ..... 1070

Effects of Nitrogen and Phosphorus on $N_2O$ Emissions from Leymus Chinensis and the Underlying Microbial Mechanisms ..... 1071

Effects of plant hormone on microbial community in soil under conservation tillage .. 1072

Towards Smart Fertilization: Building a Dynamic Rhizosphere $NH_4^+/NO_3^-$ Model under the GiP Framework for Drastically Improved NUE ..... 1073

Crop improvement for nitrogen and phosphorus use efficiency in rice ..... 1074

## Session 303006: Rhizobiont for High Nutrient Use Efficiency ..... 1075

The power of the less productive: understanding the links between diversity and belowground traits of wild, landrace and modern crops ..... 1075

Maintaining sulfur supply to rhizobia delays nodule senescence in soybean ..... 1076

One-time root-zone nitrogen application enhances nitrogen utilization and yield of faba bean by reducing nitrogen loss in the plateau of southwestern China ..... 1077

Soybean rhizospheric carbon metabolism modulated by neighbouring oat through increased isoflavonoids ..... 1078

Contrasting rhizosphere strategies of maize: How drought severity and duration affect root and rhizosphere traits in soils of varying texture ..... 1079

Genotype-Specific Rhizosphere Strategies for Phosphorus Acquisition in Tea Plants under Organic Substitution ..... 1080

Diversified cropping systems with complementary root growth strategies improve crop adaptation to and remediation of hostile soils ..... 1081

Cross-kingdom nutrient exchanges in the plant-arbuscular mycorrhizal fungi-bacteria continuum ..... 1082

Integrating plant–microbial diversity and mixed litter decomposition to enhance nutrient coupling and productivity in intercropping systems ..... 1083

Rhizosphere bacterial communities mediate host genetic effects on agronomic traits in soybean ..... 1084

Rhizobiome Partners to Optimize Nutrient Transfers from Soil to Plants ..... 1085

Screening groundnut genotypes for their nutrient efficiency in calcareous soils ..... 1086

AMF modulation of sweet potato plant performance and rhizosphere microecology depends on soil potassium availability: shared and differential strategies ..... 1087

Drivers of Potassium Efficiency in Sweet Potato: Genotypic Variation, Partitioning Dynamics, and AMF-Mediated Rhizosphere Optimization ..... 1088

Mycorrhizal solubilization of phosphate rock increases arsenic accumulation in Pteris vittata: Trade-off root strategies and dual P-transporter pathways ..... 1089

Bioprospecting soil bacteria to increase sulfate release from elemental sulfur in tropical soil ..... 1090

Nitrogen form-induced spatiotemporal coupling of root growth and phosphorus uptake ..... 1091

Nitrogen use efficiency of intercropping and its drivers: a global meta-analysis ..... 1092

Mild to moderate drought stress reinforces the role of functional microbiome in promoting growth of a dominant forage species (Neopallasia pectinata) in desert steppe ..... 1093

Instant organic carbon addition increasing the soil phosphorus availability in calcareous soil ..... 1094

Soil C:P stoichiometry regulating microbial-mediated phosphorus turnover fluxes in calcareous soil ..... 1095

## Session 303007: Sustainable Phosphorus Use in Agroecosystems: New Approaches to Optimizing Nutrient Management and Ecosystem Functionality ..... 1096

Nutrient Management and $N_2O$ Emissions from Agricultural Peatlands in Ireland ..... 1096

Enhancing soil phosphorus activation and microbial phosphorus cycling via increasing soil moisture stability in maize production ..... 1097

Phosphate rock and microorganisms as a sustainable alternative to soluble P fertilizers in tropical soil ..... 1098

Phosphorus mineralization potentials of some soil amendments applied to degraded tropical Ultisol ..... 1099

Biotechnological Strategies to Enhance Phosphorus Use Efficiency in Soybean/Maize Cropping Systems ..... 1100

Rainfall thresholds and scale-dependent hydrological dynamics of phosphorus speciation in nested purple soil catchments ..... 1101

Phosphorus supply intensity and neighboring alfalfa: effects on maize growth, phosphorus uptake, and interaction intensity ..... 1102

The Art of Breeding Microbial Communities: Unlocking Soil Phosphorus through Artificial Selection ..... 1103

Phosphorus availability and legacy in highly weathered soils: unveiling the interplay with soil aggregation across diverse agricultural land uses as integrated systems ..... 1104

Effectiveness of using the poultry-litter biochar pyrolyzed by different processes on soil available P ..... 1105

Rhizosphere AMF-Bacteria Synergy Driving Soil Phosphorus Activation in Maize//Soybean Intercropping ..... 1106

Enhancing the functionality of agricultural soils in Mediterranean regions with biobased P fertilizers: nutrient cycling and soil microbial communities ..... 1107

Evaluating the phosphorus release efficiency of duo-biochar to spring wheat ..... 1108

Effects of organic fertilizer substitution on soil inorganic phosphorus (P) fractions and dynamics at the aggregate level: evidence from P fractionation and $^{33}P$ isotopic exchange kinetics ..... 1109

Trait-mediated rhizosphere phosphorus strategies drive functional complementarity among coexisting desert shrubs ..... 1110

Phosphorus in agricultural soils: status and dynamics ..... 1111

Optimizing global cropland management to advance phosphorus sustainability ..... 1112

Impact of Combined Manure and Mineral Fertilizer on Phosphorus Dynamics in Paddy and Drained Paddy Systems: Transitioning to Soybean Cultivation ..... 1113

Characteristics of soil phosphorus profile distribution in degraded black soil areas and effects of tillage patterns on root zone phosphorus supply barriers ..... 1114

Does particle size of digestate-derived biochar affect phosphorus losses and fertilizer value? Evidence from a lysimeter study in a temperate soil. ..... 1115

Cultivar-Dependent Cluster Root Strategies Underpin Phosphorus Use Efficiency in Macadamia Grown Under Low Phosphorus Conditions ..... 1116

Organic P Mineralization in Agricultural Soils: Process Dynamics and Microbial Drivers ..... 1117

Incorporating Chinese milk vetch and rice straw promoted inorganic phosphorus mobilization through assembling phosphate-solubilizing bacteria in rhizosphere ..... 1118

Multi-benefits of wastewater phosphorus recovery for croplands in China ..... 1119

Land use controls soil phosphorus pools but not sorption mechanisms: insights from piecewise structural equation modelling ..... 1120

Long-term biochar application influences phosphorus and associated iron and sulfur transformations in the rhizosphere ..... 1121

Molecular-level understanding of transformation mechanisms of P in the calcareous agricultural soils ..... 1122

Earthworms enhance soil phosphorus cycling but plant responses differ among earthworm ecological categories ..... 1123

An innovative approach for measuring soil microbial biomass P ..... 1124

Sulphur Impregnated Biochar Synchronizes Phosphorus Release from Occluded Pools while Enhancing Carbon Stabilization ..... 1125

Keystone microbes mediate root traits and phosphorus uptake to enhance maize crop productivity in intercropping systems ..... 1127

Seabirds Bearing Light ..... 1128

Integrating regional critical boundaries and nitrogen-phosphorus limitation for global water quality ..... 1129

Exploring characterization methods and thresholds of carbon-phosphorus ratio for promoting crop growth and microbial phosphorus activation ..... 1130

Long-term green manuring increases phosphorus availability in soil by modifying microbial functional genes and enzyme activities ..... 1131

Long-term Biochar Application Enhances Carbon-Phosphorus Co-stabilization and Mitigates Methane Emissions in Flooded Rice Systems ..... 1132

Iron-based Adsorbents for Wastewater Treatment and Phosphorus Recovery ..... 1133

Recycling lake sediment for use in agriculture: insights from laboratory and field experiments ..... 1134

# 304 Soil Engineering and Technology/Soil Engineering/Soil Analysis Technique .....1135

## Session 304003: Can Enhanced Rock Weathering Capture and Store Atmospheric $CO_2$? Its Expectations and Limitations .....1135

Direct evidence for basaltic mineral weathering in cropland revealed by X-ray powder diffraction analysis ..... 1135

Pedogenic Carbonates and Calcimetry Near Detection Limits: Field-scale weathering dynamics in wollastonite-amended clayey/acidic soils .....1136

Reframing Carbon Accounting in Enhanced Rock Weathering: Counterfactuals, stoichiometry, and MRV implications .....1137

Subsurface and surface transport of crushed basalt ..... 1138

Reframing Soil Carbon Stabilization: The Reactive Mineral Sink (RMS) Model and Its Synergy with Enhanced Mineral Weathering .....1139

Impact of Enhanced Silicate Rock Weathering on Soil $CO_2$ Dynamics in Agricultural Field: Field Monitoring and Numerical Simulation .....1140

Can Silicate Rock Powder Replace Agricultural Lime and Sequester Carbon in Acid Soils? – Field and Lab Studies .....1141

Column experiment and numerical simulation for quantification of carbon fixation by enhanced rock weathering .....1142

Reconnecting geology and soil science for a broader One Health framework: Insights from Enhanced Rock Weathering .....1143

Exploring Basalt Weathering for Mitigating Greenhouse Gas Emissions in Rice Paddy System ..... 1144

Impact of soybean cultivation on basalt weathering in agricultural system ..... 1145

Wollastonite reshapes soil organic carbon fraction dynamics and enhances carbon sequestration potential .....1146

The Impact of Enhanced Rock Weathering on Soil Carbon Dynamics: A Global Meta-Analysis of Environmental and Soil Factors .....1147

Enhanced weathering using blast furnace slag(BFS) for carbon sequestration in soil .. 1148

Mechanisms of Carbon Sequestration through Bacillus-Enhanced Basalt Weathering on the Soil Priming Effect ..... 1149

Second-year effects of basalt application on maize growth and soil carbon sequestration under field conditions. ..... 1150

**Session 304004: Engineering Technology System for Efficient Quality Improvement of Obstructed Soil ..... 1151**

Soil Re-engineering – A New Approach to Improve Crop Productivity on Constrained Sandy Soils in Water-Limited Environments in Western Australia ..... 1151

Combined Application of Straw and Biochar: A Synergistic Strategy to Enhance Fertilizer Efficiency, Boost Yield, and Reduce Greenhouse Gas Emissions in Northeast China .. 1152

Engineering Technology and Practice of Microbial-Synergized Organic Material Amelioration in Albic Soil ..... 1153

Subsoil Mixed Profile Reconstruction Technology ..... 1154

Ecological Prevention and Control of Early-Stage Gully Erosion in Black Soils: Concepts, Mechanisms, and Integrated Technologies ..... 1155

Tillage and straw return alleviate soil compaction in Northeast China: From pore structure to root development and crop productivity ..... 1156

Bacterial richness enhances the thermostability of soil organic matter: long-term perspective ..... 1157

Carbonic Anhydrase Enabled Synergies for Enhanced Microalgal $CO_2$ Fixation: From Enzyme Production to Engineered Microbial Consortia ..... 1158

## Session 304007: Frontier Technologies for Soil Analysis: From Single-Cell to Nanosensors ..... 1159

Monitoring Ecological Rehabilitation of Degraded Soils by Human Activities Using Thermal Indicators of Soil Organic Matter ..... 1159

Developing a diffusive gradients in thin films (DGT) technique for large-scale and high-resolution mapping of labile potassium in soils ..... 1160

Single-cell exploration of the microbiota driving soil phosphorus mobilization: from single-cell Raman to high-throughput fluorescence profiling ..... 1161

The Soil iMAPS Initiative: a global network to map the single-cell in-situ metabolic atlas for soil ..... 1162

Loosely bound mobile metal ions distribution across arid landscapes ..... 1163

Raman-based flow cytometry for single-cell microbial phenotyping ..... 1164

Evaluation of ion selective electrodes for monitoring plant nutrients ..... 1165

Designing drought-resilient plant microbiomes using single-cell Raman spectroscopy 1166

Micro-CT scanning as a tool for analysing comparative root architecture of pasture species ..... 1167

Evolutionary engineering of microbial communities to combat aluminum toxicity in acidic soils ..... 1168

Discrimination and Quantification of Soil Nanoparticles by Dual-Analyte Single Particle ICP–QMS ..... 1169

Quinolone-mediated metabolic cross-feeding develops aluminium tolerance in soil microbial consortia ..... 1170

From lab to field: An open-source, low-cost toolkit for soil $CO_2$ respiration research ..1171

Nitrogen-fixing seed endophytes synergize with soil functional microbiota to enhance rice nitrogen supply ..... 1172

In situ Non-destructive Imaging of Roots from GFP-Expressing Plants Using a Novel Fluorescence Minirhizotron with Automated Intensity Measurement and CNN-based TRL Estimation ..... 1173

# 305 Soil Degradation Control, Remediation and Reclamation/Soil Remediation/Environmental Micro-Plastics .....1174

**Session 305001: Deciphering the Soil-Pollutant Nexus: Biogeochemical Frontiers for Soil Health and Sustainable Ecosystems .....1174**

Green Surfactant Remediation of Petroleum Hydrocarbon-Contaminated Soil and Bacterial Community Response .....1174

Contrasting soil functional responses to climate change in restored and spontaneously colonized mine tailings ..... 1175

Geochemical Fractions of Pb and Ni in Orchard Soils and Ecological Risk Assessment Using Pollution Indices .....1176

Intensified Production of Hydroxyl Radical from Iron-Manganese Synergistic Coupling during Soil Oxygenation: Driven by Iron-Induced Manganese Redox Cycling and Peroxo Complex Formation ..... 1177

Bioremediation Mechanism of Polycyclic Aromatic Hydrocarbon Contaminated Soil Based on Signal Molecular Regulation Strategy under Low Temperature Stress ..... 1178

From Collieries to Continents: Deciphering the Soil-Pollutant Nexus in Coal Mine Landscapes ..... 1179

Microbial Methylation of Mercury Mediated by Soil Organic Matter: Progress and Prospects ..... 1180

From Pollution to Solution: Microbial Insights and Novel Bacteria for Biodegradation of Organochlorine in Coastal Wetland Soil .....1181

Mapping soil deposition of antibiotics at municipality-scale in Brazil .....1182

Overlooked Ecological Risks of Chlorinated Pollutants in Anaerobic Soils: Coupling Microbial Dehalogenation with Methanogenesis .....1183

Enhanced Fomesafen Microbial Degradation in Anaerobic Soils by Glucose: Degradation Characteristics Under Different Redox Conditions ..... 1184

Elevated $CO_2$ enhanced PFOA removal and reduced $N_2O$ emissions in soil: evidence from a FACE experiment ..... 1185

Enzyme Activity and Biological Quality Scores in Tropical Soils Exposed to Cadmium and Chromium ..... 1186

Micro-scale redox heterogeneity governs chromium mobility and reoxidation in flooded industrial soils with contrasting properties ..... 1187

Elucidating Arsenic–Soil Mineral Interactions at the Microscopic Interface: Insights into Arsenic Geochemistry based on mechanistic speciation ..... 1188

Microbial Degradation of Soil Microplastics (MPs) Related to Greenhouse Gas Emissions ..... 1189

Multi-Omics Metabolic Models of Coupled Dechlorination and Methanogenesis Enhance Pollution and Carbon Reduction in Anaerobic Soils ..... 1190

Neglected contributions of residual herbicides at various levels on soybean root rot: links with time-series changes in non-target soil microbial communities and functions ..... 1191

The SIMULATE Project: evaluating climate-warming impacts on metalliferous mine tailings to guide restoration strategies in semiarid landscapes ..... 1192

Rethinking Restoration: Functional Trajectories of Soil-Vegetation Systems in Restored vs. Spontaneously Colonized Metalliferous Mine Tailings under a Changing Climate 1193

Photochemical characterization of paddy water: Formation of reactive intermediates for micropollutant degradation ..... 1194

Risk Assessment of Agricultural Plastic Film and Microplastics in Soil-Water Systems: Fate, Transport, and Ecological Implications ..... 1195

Microalgae enhance the ameliorative effects of organic materials on soil treated by thermal desorption ..... 1196

Quantifying Soil Health in Cd-Contaminated Soil Remediation: Methodology Optimization and the potential role of Soil Viruses ..... 1197

The Passivation Remediation of Weakly Alkaline Cadmium-Contaminated Farmland Soil ..... 1198

Long-Term Ecological consequences of the Proton Launch Vehicle First Stage Falling: Preliminary Results of the Comprehensive Case Study in Central Kazakhstan ..... 1199

Analysis of Traits and Prediction of Angiosperm Species of Plant-Hyperaccumulators of 17 Heavy Metals and Metalloids: Initial Results ..... 1200

Environmental Prevalence and Application of Organohalide-respiring Bacteria in Remediation ..... 1201

Literature Data-Driven Prediction of Soil and Groundwater Pollutant Distribution at Regional Scales ..... 1202

The genesis of nano-colloid-bound Cd and As: from climatic and pedogenic controls to global projections ..... 1203

Divergent responses of alfalfa-soil nitrogen cycling to PE and PLA microplastics: A metabolic and microbial perspective ..... 1204

Inhibition mechanism of hexachlorocyclohexane isomers on different methanogen metabolism ..... 1205

Response and functional restructuring of micro-food webs in heavy metal-contaminated soil ..... 1206

Effects of methane oxidation on microbial mercury methylation in typical paddy soils ..... 1207

Aluminum and microplastic release from reflective agricultural films disrupt microbial communities and functions in soil ..... 1208

MICROBIAL REFUGEE UNDER SHRUBS LIMITS SOIL COPPER CONTAMINATION EFFECTS ..... 1209

Microbial community assembly and metabolic pathways drive the enrichment of stable DOM under long-term conservation tillage practices in sloping farmlands ..... 1210

Soil metabolic processes influenced by rice roots co-regulates the environmental evolution of antibiotic resistome ..... 1211

Specific metabolites modulate core microbes and microbial interactions to drive fomesafen dissipation in the soybean rhizosphere ..... 1212

Speciation Distribution, Transformation, and Interfacial Interaction Mechanisms of Heavy Metals and Phosphate in Contaminated Farmland Soils ..... 1213

One Health Implications of Treated and Untreated Wastewater Irrigation: Evidence from farmer-managed systems in Northern India ..... 1214

Coupling Pollution Screening with Ecotoxicological Response: Critical Thresholds, Aromatic Stress, and Dominant Degraders in the Loess Plateau ..... 1215

Research on Soil Reconstruction Technology Based on Sand-Clay Compound Ratio in Grassland Open-Pit Mining Areas ..... 1216

## Session 305002: Enhanced In Situ Bioremediation for Contaminated Sites .....1217

Genotypic Variability in Bioaccumulation and Dietary Risks of PFAS across 30 Wheat Cultivars: A Field Assessment .....1217

Comparative Study on the Efficiency of Multiphase Extraction Combined with Bioremediation and Thermal Enhanced Coupling Process .....1218

More Than Containment: An Innovative Attempt to Solve Groundwater Contamination at Landfills —— The Application of a Nation's First Full-Process Technical System Integrating Source, Pathway, and End-of-Pipe Treatment .....1219

Earthworms and Crop Varieties Mediate the Effects of Nano-Hydroxyapatite on Soil Biochemical Characteristics and Cadmium Uptake by Plant ..... 1220

Remediation of Cadmium-Contaminated Soil via the Coupling of Marigold-Water Spinach Intercropping and Passivation .....1221

Root acid phosphatases and microbial biomass phosphorus induced Cd tolerance and P acquisition in wheat inoculated with P solubilizing bacteria. .....1222

Nitrogen Transfer and Cross-feeding Between Azotobacter chroococcum and Paracoccus aminovorans Promotes Pyrene Degradation .....1223

Biohydrogen Utilization in Legume-rhizobium Symbiosis Reveals a Novel Mechanism of Accelerated Tetrachlorobiphenyl Transformation .....1224

Variations in root functional traits facilitate the adaptation of pioneer plants to rare earth element mine tailings ..... 1225

Phytoremediation of heavy metals in soils of the Christchurch Red Zone .....1226

Transforming Spent Coffee Grounds (SCG) into an Environmental Asset- Its Characterization and Optimization for Soil Amendment and Remediation Applications .....1227

Differential responses of phoC- and phoD-harbouring bacterial communities to cadmium stress and microbial inoculation in a rapeseed pot system .....1228

Metabolic complementary Between Cupriavidus and ..... 1229

Pseudomonas Facilitates 2,4,6-Trichlorophenol Degradation ..... 1229

Root foraging for metals as a key trait of hyperaccumulators may be obscured in soil systems: Evidence from experiments and a meta-analysis ..... 1230

Sulfate-Amended In Situ Bioremediation of Chloroethene-Heavy Metal Co-Contamination: Mechanisms, Microbial Responses, and Pilot-Scale Validation ..... 1231

Phytomining of rare earth elements from phosphogypsum waste heaps using silver birch (Betula Pendula Roth) ..... 1232

Thermally Enhanced Biodegradation Mechanisms of Chloroethenes and BTEX Co-Contaminants in Groundwater: Insights into Microbial Functional Gene Enrichment and Biogeochemistry ..... 1233

Estimating Petroleum Hydrocarbon Plume Volume and Mass from Sparse and Zero-Inflated Soil Data Using INLA-SPDE ..... 1234

Potential bacterial resource for bioremediation of organochlorine pesticides and flame retardants recognized from forest soil across China ..... 1235

Historically Exposed Soil Microbiomes Serve as Living Bioenhancers for Antibiotic Remediation ..... 1236

Biochar and microorganism-assisted remediation of brownfields ..... 1237

Remediation potential of oil-contaminated soils, under biochar and mineral salts influence ..... 1238

Characterizing Temperature-Dependent Dissipation Kinetics of Co-Mingled Contaminated Soils ..... 1239

Temporal Dynamics and Metabolic Profiling of Vetiver Root Exudates Under Atrazine Stress ..... 1240

Sequential Causal Machine Learning Assisted Design of Biochar for Laccase Immobilization ..... 1241

Effects of Amendments on the Anaerobic Bioremediation of Organohalides in Contaminated Soil and Groundwater ..... 1242

In Situ Enhanced Reductive Dechlorination for Chlorinated Aliphatic Hydrocarbon–Contaminated Sites ..... 1243

Dual inhibition mechanisms drive antagonistic effects during phenanthrene and pyrene co-degradation by Pseudoxanthomonas: Pathway competition and substrate pReferences ..... 1244

## Session 305003: Integrated Remediation and Utilization Strategies for Degraded Soils in Mined Lands ..... 1245

The Fundamentals of Disturbed Land Reclamation ..... 1245

Ecological restoration of semi-arid, PTE-enriched toxic mine tailings through organic amendments and microclimatic regulation via fascines ..... 1246

Exogenous Chemicals Used to Alleviate or Salvage Plants under Flooding/Waterlogging Stress: Their Biochemical Effects and Perspectives ..... 1247

Ultrafast and high-capacity gold retrieval via cascade reduction ..... 1248

Comparison for physico-chemical properties of restored soil with two types of vegetation at abandoned coal mine in Gangwon province, South Korea ..... 1249

Upcycling Rare Earth Hyperaccumulator Biomass into Functional CaS:Ce Phosphors: A Coupled Remediation–Utilization Strategy for Degraded Rare Earth Mine Soils ..... 1250

The dependency of spontaneous vegetation growth on soil and tailing material properties of mine residue deposits at different climates in Namibia ..... 1251

Biochar-loaded AM fungi coupled with Arundo donax enable targeted red mud remediation via valency-specific metal detoxification and soil function recovery ..... 1252

Formation and Migration Patterns of Polycyclic Aromatic Hydrocarbons in Underground Coal Fires: A Case Study of a Typical Coal Fire Zone ..... 1253

The removal mechanism of Pb2+ from wastewater by phosphorus-modified biochar . 1254

Vetiver Grass Induced Changes in Soil Acidity, Electrical Conductivity and Soil Organic Carbon in Mine-Affected Soils over two Rehabilitation Periods ..... 1255

Root acquisition-defense strategies of pioneer plants in heavy metal contaminated mining areas ..... 1256

Ecological package-driven early reclamation of open-pit mines in arid and semiarid regions: Insights from soil bacterial communities, functional genes and physicochemical properties ..... 1257

**Session 305005: Micro-and Nano-Plastics in the Soil: From Pollution to Solution ..... 1258**

High-Throughput Detection Method for Microplastics Based on Fluorescence Spectroscopy and Machine Learning ..... 1258

Beyond Detection: An Intelligent Raman-Based Exploration of the Microplastic Full-Lifecycle ..... 1259

Weathered microplastics trigger metal transformation ..... 1260

Precise tracking of nanoparticles in plant roots ..... 1261

Impact of microplastics on nitrate reduction in agricultural soils ..... 1262

Migration Behaviors of Typical Microplastics in Soil with Different Textures by Rainfall Induced Surface Runoff ..... 1263

Anthropogenic activities and hydrologic environment of Danjiangkou Reservoir regulate soil microplastics in the water level fluctuation zone ..... 1264

Microplastic transport in soil by nematodes ..... 1265

Friend or foe? Can microplastics ever be our ally? ..... 1266

From field to greenhouse: evaluating microplastics pollution and its potential impact on Mediterranean agricultural soils ..... 1267

Comparative Degradation and Environmental Impacts of Biodegradable Mulch Films in Agricultural Soils of the United States and China: Toward Sustainable Plastic Management ..... 1268

From snowpack to soil: microplastic pathways in alpine ecosystems ..... 1269

Mineralization determines microplastic effects on soil organic carbon ..... 1270

Do biodegradable PBAT plastic films alter C–N coupling in ways that benefit soil functioning? ..... 1271

Identification and characterization of a biodegradable plastic mulch film degrading bacteria strain PBAT-1 in the soil ..... 1272

Micro-nanoscale polystyrene and polyvinyl chloride co-exposure impacts the uptake and translocation of toxic elements and pesticides by lettuce and wheat ..... 1273

Impacts and degradation of microplastics (MPs) in agricultural soil ..... 1274

Ecological Risk Assessment of Microplastics in Soil Based on Probability Distribution and Machine Learning ..... 1275

Microplastics disrupt nitrogen-fixing bacterial community with consequences for plant growth ..... 1276

Aging of plastic polymers used in agriculture affects sorption of pesticides and their subsequent release ..... 1277

Mineralization and transfer of polymer-derived carbon from biodegradable mulch into the soil microbial biomass and organic matter pool ..... 1278

Characterization of microplastics using pyr-GC/MS and their leaching and runoff behavior in soil ..... 1279

Assessment of the reliability to extract soil microplastics by a flotation sieving method ..... 1280

National Inventory of Plastic Mulch Residues in Chinese Croplands from 1993 to 2050 ..... 1281

Harnessing Trichoderma spp. to Enhance Foliage Yield and Quality of Lettuce (Lactuca sativa L.) in Microplastic-Contaminated Soils: A Sustainable Strategy for Global Soil Health and Food Security ..... 1282

Revealing Microplastic Contamination in Coastal Soils in Southern Italy via ATR-FTIR and SEM ..... 1283

Effects of microplastics on microbial communities and antibiotic resistance genes in the soil-plant system ..... 1284

Short-Term Exposure to Polystyrene Micro- and Nanoplastics modifies Soil Nutrient Availability without affecting Lettuce Productivity in Tropical Climate ..... 1285

Determining a Carbon Mass Balance and Active Degraders of Isotopically Labeled Polylactic Acid (PLA) in Soil ..... 1286

Temporal Dynamics of Microplastic Accumulation and Soil Quality under Plastic Mulching in Mediterranean Soils ..... 1287

Microplastic Quantification in Urban Farmland Soils Using Elutriation: Insights from a Compost-Amended Site ..... 1288

Effects of microplastics on litter decomposition in Shengjin Lake wetlands ..... 1289

Screening of microplastic-degrading bacteria and their effect on lettuce growth under pollution stress ..... 1290

Earthworms Mediated Fate of Microplastics in Soil ..... 1291

Long-term Field Evidence on Microplastic Generation and Altered Soil Functioning by Biodegradable Film Mulch ..... 1292

Ecological risk and machine learning prediction of microplastic pollution in peatlands ..... 1293

Changes in the dispersivity of soil substrates after contamination with microplastic polystyrene ..... 1294

Impact of Microplastic Pollution in U.K. Woodland Soil: Evidence from a Long-Term Soil Burial Experiment ..... 1295

Quantification of Micro- and Nanoplastics in Agricultural Soil and Application in Japan ..... 1296

Microplastic Contamination in Soil around the Aral Sea in Uzbekistan ..... 1297

Characterization of Small Microplastics in Japanese Agricultural Soils and Their Effects on Soil Aggregate Structure ..... 1298

Oxidized Residues Accelerate Phosphorus Immobilization via Enhanced Surface-induced Nucleation ..... 1299

Ten years of microplastics in the soil-plant system research-what have I learned? ..... 1300

Uptake Process and Toxicity Mechanism of Microplastics and Phthalate Esters in Plant ..... 1301

Development of a protocol for the extraction and quantification of nanoplastics in agricultural soils ..... 1302

Chemical and biochemical approaches to assess the biodegradation of polyhydroxyalkanoates in soil ..... 1303

Soil metabolome impacts the formation of the eco-corona and adsorption processes on microplastic surfaces ..... 1304

Changes in Soil Biological Activity Induced by Increasing Doses of Aged Microplastics in Agricultural Soil ..... 1305

Effects of secondary microplastics input on the mineralization of soil organic carbon 1306

Interfacial Colloidal Behavior of Microplastic-Pollutant Complexes and Its Regulation by Environmental Conditions ..... 1307

Soil microplastic risk from microcosms to field surveys: nematode bioindicators across scales from individuals to micro-food webs ..... 1308

Before You Measure: How Sampling Strategies Shape Microplastics Quantification in Soils ..... 1309

Synthesis of Hierarchical Porous Magnetic Zeolite-Biochar Composites from Solid Waste for Micro/Nanoplastics Adsorption in Soil-Groundwater Systems ..... 1310

How does plastic pollution influence soils and soil fungal communities in temperate alluvial forests ..... 1311

Insights into the vertical transport of microplastics in agricultural soil: impact of soil pore networks ..... 1312

## Session 305006: New Pollutants in Soils & Agro-Environmental Health ..1313

Nanotoxicomics: Cellular-subcellular Impact of Nanoparticles in Plants ..... 1313

Biological Strategy for Identification and Elimination of Organic Pollutants in Agro-Environments ..... 1314

Boron in Soil: Linking Microbial Responses and Plant Performance ..... 1315

Chemical characterization, fluorescence properties, and photochemical reactivity of natural dissolved organic matter ..... 1316

Enhanced Sorption of Per- and Polyfluoroalkyl Substances by Soils from Water via Cation Bridging Interaction ..... 1317

ENVIRONMENTAL RISK OF GEOACCUMULATION AND TRANSMISSION OF HEAVY METALS IN TAILING DAMS WITH RADIOACTIVE ELEMENTS ..... 1318

Bioremediation of soil contaminated with boron by using biochar and barley plants ...1319

Evaluation of nano-PbO and macro-PbO transformation in soil-plant system based synchrotron methods ..... 1320

A Bacillus paramycoides strain and its application in wastewater treatment ..... 1321

Phototransformation of New Organic Contaminants and Associated Biological Effects as Mediated by Smectite Clays ..... 1322

Biochar downsizing: From bulk to nanoscale solution in soil remediation and contaminants immobilization ..... 1323

Risk Ranking of Antimicrobial Resistance Across One Health Sectors: Leveraging Long-Read Sequencing and Methylation Analysis ..... 1324

Global ecological and health risks of PFAS in surface soil ..... 1325

Can Machine Learning Predict Plant Uptake of Per- and Polyfluoroalkyl Substances from Soils? ..... 1326

Functional Resilience and Network Reorganization: How Plant-Associated Microbiome Maintain Ecosystem Services Under Antibiotic Pressure ..... 1327

Spatial Compartmentalization Overrides Antibiotic Effects in Shaping Plant-Associated Bacterial Communities: Insights from the Lettuce Microbiome ..... 1328

Distribution and Fate of Per- and polyfluoroalkyl Substances in Sludge and Biosolids from Municipal Wastewater Treatment Plants across the United States ..... 1329

Microbially Mediated Degradation Processes and Mechanisms of Flame Retardants in Soils ..... 1330

Soil Biogeochemical Responses to Acid Mine Pollutants in Coal-Mined Inceptisols of Assam, India ..... 1331

Bacterial Extracellular Vesicles as Vectors of Antimicrobial Resistance in Agricultural Soils ..... 1332

Biotransformation of tire-derived 6PPD and 6PPD-Q and metabolism alteration in rice plants under different exposure routes ..... 1333

Migration and Mitigation of Manure-borne Antibiotic Resistance Genes in Soil-vegetable Systems ..... 1334

Photodegradation of clindamycin by biochar-derived dissolved organic matter is simultaneously regulated by ROS generation and binding effect ..... 1335

Occurrence of pesticide residues under different land uses across Europe ..... 1336

Sulfamethoxazole Transformation by Heat-Activated Persulfate: Linking Transformation Products Patterns with Compound-Specific Isotope Analysis ..... 1337

Fluorinated Pesticides Pose Emerging Global Environmental Risks ..... 1338

Screening Non-Antibiotic Antimicrobial Agents in Environmental Matrices Using Interpretable Machine Learning and High-Resolution Mass Spectrometry ..... 1339

Antibiotic Residues, Microbial Ecology, and Greenhouse Gas Production in Manure: An Integrated One Health Perspective ..... 1340

Adsorption of antibiotics by natural clay minerals ..... 1341

Exposure to cypermethrin pesticide disturbs the microbiome and disseminates antibiotic resistance genes in soil and the gut of Enchytraeus crypticus ..... 1342

Nationwide Screening and Priority Ranking of Plastic Additives in Agricultural Soils of China ..... 1343

Effects of predator-prey interactions on driving the evolution of bacterial antibiotic resistance ..... 1344

Mitigation of antibiotic resistance genes in agricultural soil by Fe/Mn oxides functionalized biochars via suppressing horizontal gene transfer ..... 1345

Plastic and Non-Plastic Microfibre Biodegradation in Soil: Monitoring the Impact ..... 1346

Ecological Risks of Antibiotic Residues and Bioremediation in Agricultural Soils ..... 1347

Adsorption Study of Sulfamethoxazole and Ciprofloxacin on Soil and Biochar Composite ..... 1348

Climate-Driven Soil Processes Controlling the Fate of Sulfamethoxazole and Environmental Antimicrobial Resistance in Tropical Agro-Riverine Systems of Vietnam ..... 1349

Legacy Phosphorus and the Environmental Health of Agricultural Soils in South Korea ..... 1350

Ligand-to-Metal Charge Transfer Driven Transformation of Ferrihydrite and its Effect on Arsenic Repartitioning ..... 1351

Advancing Microplastics Research and Mitigation through Nuclear Science and Case Studies ..... 1352

Isotopic Techniques to Assess the Fate of Antimicrobials and Implications for Antimicrobial Resistance in Agricultural Systems ..... 1353

Synthesis and isotope analysis of labelled sulfamethoxazole to trace persistence and natural degradation in the field ..... 1354

Non-monotonic Reproductive Toxicity of F-53B in Earthworm: Environmental Relevance from Northwest China Industrial Soils ..... 1355

Remediation of Prometryn-Contaminated Soil through Microbial-Phytoremediation Synergy: An Integrated Strategy for Soil Degradation Control and Sustainable Reclamation ..... 1356

Antibiotic resistance at environmental multi-media interfaces through integrated genotype and phenotype analysis ..... 1357

Pollution characteristics, sources and risk assessment of per- and polyfluoroalkyl substances (PFASs) in river water, sediments, soils of the Inner Mongolia Section of the Yellow River ..... 1358

Persulfate activation by Schwertmannite degrading phenanthrene in soil ..... 1359

Fate of Di(2-ethylhexyl) Phthalate (DEHP) in Agricultural Soil: The Role of Environmentally Characteristic Microplastics ..... 1360

Contrasting effects of arsenic and cadmium on PFAS sorption and transport in soils: Mechanistic insights and mathematical models ..... 1361

## Session 305007: Organohalide Biogeochemical Cycling and Remediation in Soil ..... 1362

Spatiotemporal pattern and Mitigation Potential of Carbon Emissions from Ex-Situ Thermal Desorption for Contaminated Sites in China ..... 1362

Microbial Communities and Metabolic Potential for Reductive Debromination of 2,4,6-Tribromophenol in Deep-Sea Cold Seep Sediments ..... 1363

Microbial reductive dehalogenation of emerging organohalides and its application in bioremediation ..... 1364

Soil Organic Carbon Prediction Based on Vis–NIR Spectral Classification Data Using GWPCA–FCM Algorithm ..... 1365

A Novel Sample Selection Strategy for Instance-based Transfer Learning in Local Soil Organic Carbon Estimation ..... 1366

Design of effective materials to collaborate with microorganisms in reductive remediation of chlorinated organic pollutants ..... 1367

Anaerobic biochemistry at the core of reductive dehalogenation in soil and groundwater ..... 1368

The Marine Environment as a Rich Source of Diverse Anaerobic Organohalide-Respiring Bacteria ..... 1369

Microbial defluorination of PFASs by native consortia enriched from PFASs and CAHs co-contaminated sites ..... 1370

Mapping the Co-Occurrence of Organohalides and Microbial Dehalogenation: A Microbial Biochemistry Framework for One Health ..... 1371

Stimulating Feammox-Associated Microbial Communities in Iron-Rich, Acidic Sediments from AFFF-Impacted Sites to Promote PFAS Defluorination ..... 1372

N-enriched biochar-iron cobalt mineral system for biomimetic reductive dehalogenation ..... 1373

Demonstration Verification of Characterization Technology for DNAPLs in Typical Chemical Sites ..... 1374

Microbially mediated organohalide cycling in soil ..... 1375

Organic Carbon Availability for Sulfate-Reducing Bacteria Governs the Dechlorination Reactivity of Biogenic Sulfidated Nanoscale Zero-Valent Iron ..... 1376

Community Diversity Determines Colonization and Performance of Organohalide-respiring Bacteria ..... 1377

Hotspots for Microbial Dehalogenation of Persistent Organohalide Pollutants ..... 1378

Interactions of Zero-Valent Iron with Groundwater Environmental Components and Their Effects on Dechlorination ..... 1379

Anaerobic degradation of chloromethane by ”Candidatus Chloromethanibacter formatiformans“ strain JHJ ..... 1380

Concerted microbial synergy and syntrophy facilitates anaerobic mineralization of 2,4-dichlorophenoxyacetic acid .....1381

Enhancing Electrochemical Reductive Defluorination of PFASs Using ZIF-67 Modified Cathode: Mechanistic Insights and Performance Optimization .....1382

Applying Compound Specific Stable Isotope Analysis for Characterizing the Biotransformation of Hexachlorocyclohexane Isomers by Different Methanogens .....1383

Nitrate Reduction Influences the Structure and Function of Dehalogenating Community .....1384

Coupling Sulfidated Zero-Valent Iron with Organohalide Respiring Bacteria for Remediation of Mixed Chlorinated Hydrocarbons Contamination ..... 1385

From Antagonism to Synergy: Porous Media Regulate the Coupled Degradation of Trichloroethylene by Nanoscale Zero-Valent Iron and Reductive Dechlorinating Bacteria .....1386

Rare Chlorinated Pesticide-Degrading Microorganisms from Aral Sea Sediments ..... 1387

A Field Study to Examine Applicability of a Novel Groundwater in-situ Bioremediation Method to Co-optimize Dechlorination of Chlorinated Ethenes and Subsurface Ecological Stability ..... 1388

Microbial Processes Impacting Fate and Transport of PFASs ..... 1389

Nitrous Oxide Modulates Reductive Dechlorination and other Biogeochemical Processes ..... 1390

## Session 305009: Soil Pollution by Heavy Metals and Risk Control ..... 1391

Comprehensive Assessment of Soil Heavy Metal Pollution in the Historic Center of Krakow, Poland: Geostatistical and Machine Learning Study ..... 1391

Distribution and Environmental PReferences of Potential Mercury Methylators in Paddy Soils across China ..... 1392

Trace Elements Accumulation Patterns in Cryoconites and Periglacial Soils of the Central Caucasus Mt (Russia) and Northern Tian Shan Mt (Kazakhstan) ..... 1393

Mineral-organic matter association controls colloidal arsenic mobility from soil to lake ..... 1394

Phytoremediation of Cd-Contaminated Soil: Role of Tropical Grasses in Modulating Cadmium Speciation ..... 1395

The Effect and Mechanism of Large-Scale Polymer Materials in the Remediation of Soil Chromium Pollution ..... 1396

Effect of 5-year continuous phosphogypsum application on soil quality, heavy metal accumulation, and maize growth ..... 1397

Ascorbic Acid-Based Gel for Remediation of Chromium-Contaminated Soil ..... 1398

Methylmercury Accumulation and Risk Mitigation in Chinese Paddy Soils ..... 1399

Atmospheric Deposition and Trace Element Contamination in Urban Garden Soils and Vegetables in Kingston, New York (US) ..... 1400

Bioaugmentation effects of three ecological categories of wild earthworms on phytoextraction of Sedum plumbizincicola in Cd and Zn contaminated soils of South China ..... 1401

Particle-nanoparticle transformations in metal-contaminated soils ..... 1402

Soil Trace Elements and Human Health ..... 1403

Heavy Metal Immobilization Potentials of Some Agricultural Wastes in Contaminated Arable Soil ..... 1404

Quantification of chromium and nickel lateral migration in serpentine soils via ion, colloid and particulate pathways ..... 1405

Long-Term Effects of Repeated Organic Amendment Applications on Cadmium Bioavailability: Insights from a Five-Year Pot Experiment ..... 1406

Managing Cadmium Uptake in Vegetables with Repeated Applications of Amendments: Lessons from a Multi-year Field Experiment ..... 1407

Effects of plant growth-promoting bacteria and its mechanisms towards Brassica juncea L. growth and Cd phytoextraction ..... 1408

Sulfur enhances iron plaque formation and stress resistance to reduce the transfer of Cd and As in the soil-rice system ..... 1409

Dual function of sulfur in Cd-As co-contaminated soils: enhancing phytoremediation with mustard and ensuring rice safety under drought-flood rotation systems ..... 1410

Combining multiple high-resolution in-situ techniques to understand the metals mobilization at anoxic-oxic interfaces in flooded industrial soils ..... 1411

IAA-producing and Cd-tolerant endophyte Bacillus sp. RE35 enhance Cd trap in rice roots via root cell wall remodeling during colonization ..... 1412

A Basin-Scale Synthesis of Inorganic Contamination Across Slovenia's Major Floodplains ..... 1413

Chemical Remediation of Multi metal Contaminated Inceptisol by Valorizing Calcitic and Lignocellulosic Wastes ..... 1414

Quantifying Metal Transport by Water Erosion: A Field-Based Assessment in a Semiarid Mediterranean Former Mining Area (SE Spain) ..... 1415

Stabilizing Urban Soil Lead: Long-Term Effects of Soil Amendments on Bioaccessibility and Speciation ..... 1416

Microbial Induced Carbonate Precipitation (MICP) for Cadmium Contamination Remediation coupled with Life Cycle Carbon Sequestration ..... 1417

Reduction of lead bioavailability and phytotoxicity in Pb-slag contaminated soil using soil mixing and compost-modified biochar ..... 1418

Spatial Patterns and Predictive Controls of Heavy Metals in Agricultural Ditch Network Across China ..... 1419

Study on the coupled processes of Cd and Fe transfer in the soil-rice system: a remedial strategy using functional fertilizer ..... 1420

Long-term persistence of immobilizing agents for reducing the phytoavailability of heavy metal(loid)s in contaminated soil ..... 1421

Immobilization of Arsenic and Cadmium in Alkaline Soil Using Combined Red Mud–Phosphogypsum Amendment ..... 1422

Organic Matter Regulates Soil Cadmium Bioavailability ..... 1423

Evaluation of Environmentally Important Elements from Glacial Ice-Water and Associated Glacial Sediments ..... 1424

Monitoring Cadmium in Soils, Fertilizers, and Baby Leaf Vegetables in Southern Italy: Regulatory and Environmental Insights ..... 1425

Simultaneous immobilization of arsenic and cadmium in paddy soil with co-application of birnessite and lime ..... 1426

Mechanisms and Risk Control of Chromium Uptake in Rice: The Pivotal Role of Colloidal Formation ..... 1427

Assessing Heavy Metal Pollution Levels and Associated Ecological Risks in Peatland Sediments of the Mekong Delta, Viet Nam ..... 1428

Phytoremediation of Multi-Metal Contaminated Mine Soils: Native Species Screening and Chelate-Assisted Phytoextraction ..... 1429

Speciation of Heavy Metals in Soil and Their Influencing Factors in a Tailings-Affected Area of Eastern Inner Mongolia ..... 1430

Mechanism of Auxin Regulation on Cadmium Uptake in Roots of Different Cadmium-Accumulating Rice Lines ..... 1431

Regulatory Effects of Nitrogen and Acetate on Arsenic Adsorption by Bentonite in an Anaerobic System ..... 1432

Metallomes in Soil-Crop Systems: Integrating Nutrition and Food Safety ..... 1433

α-ketoglutarate mitigates Cd accumulation and enhances Cd tolerance in rice ..... 1434

Accumulation characteristics and risk prediction of Cu and Zn contents in typical facility soils in China ..... 1435

Bioavailability and Mobilization of Colloidal Cd in Alkaline Soils of Wheat Field ..... 1436

Distinct assembly processes and ecological strategies of bacterial and fungal communities during the aging of Cd and As in soils: Fungi play a predominant role in microbial resistance ..... 1437

Source-risk-driver analysis of heavy metal pollution in karst soils: An integrated assessment in eastern Yunnan, China ..... 1438

Study on the Effects of Different Types of Humic Acids and Iron-Manganese Oxides on the Speciation of Heavy Metals in Soil ..... 1439

Colloidal Cd Mobilization During Reductive Dissolution of Cd-Birnessite by Organic Matter: Role of pH-Dependent Mineral Transformation and Organic Fractionation .... 1440

Quantitative Analysis of Heavy Metal Pollution Sources, Influencing Factors, and Delineation of Pollution Risk Areas in Mining Area Soil: A Combined machine learning and Application of Receptor Models ..... 1441

Land use shapes air-surface Hg0 exchange in karst areas ..... 1442

Machine learning-supported determination for site-specific natural background values of soil heavy metals ..... 1443

Two-stage heavy metal enrichment during carbonate rock weathering-pedogenesis: Micro-scale evidence from soil-rock interface ..... 1444

Assessment of Livestock Carrying Capacity in Typical Agro-Pastoral Transition Zones Based on Heavy Metal Pollution in Cultivated Land: The Case of Chifeng City ..... 1445

Mining-induced arsenic contamination: cascading effects on soil biogeochemistry, microbial community structure and human health risks ..... 1446

Impact of human activities on soil heavy metal pollution and its potential ecological risks of hills within Guangzhou ..... 1447

Arbuscular Mycorrhizal Fungi and Iron-Modified Peat Synergistically Drive Soil Metal(loid) Immobilization and Organic Carbon Stabilization ..... 1448

Iron (hydr)oxide-enriched Biochar for Arsenic Immobilization under Microbial Iron Reduction and Fluctuating Redox Conditions ..... 1449

Land-Use-Driven Patterns of Heavy Metal Contamination in Surface Soils ..... 1450

Large-scale nutrient management strategies shape acidification-induced risks for crop yields and food quality by cadmium ..... 1451

Efficacy of Agricultural Waste-Derived Engineered Biochar on Arsenic/Iron Dynamics and Alleviating Arsenic Risk in Waterlogged Paddy Soil ..... 1452

Dual Roles of Corticiaceae Sp. ZJ 06 In Synergetic Soil Heavy Metal Immobilization and Soil Fertility Enhancement ..... 1453

Core microbiomes of Cd-hyperaccumulators and its contribution to plant performance ..... 1454

Soil Water Regimes Control Cadmium Bioavailability and Translocation in Rice Systems ..... 1455

Aqueous and colloidal dynamics in size-fractionated paddy soil aggregates with multiple metals contaminants under redox alternations ..... 1456

Heavy Metal Contamination and associated ecological risks in Soils around Buddha Nullah drain, Punjab, India ..... 1457

Mitigation of Heavy Metal Transfer from Soil to Lettuce Using Pyrophyllite: A Soil–Plant Study ..... 1458

Content of trace elements and polycyclic aromatic hydrocarbons in soils of polar regions: variability across landscapes ..... 1459

Effect of polymeric materials on mobile forms of heavy metals the upper soil horizon at different levels of contamination in UmbricAlbeluvisols ..... 1460

Electrochemical and molecular mechanisms underlying aluminum-enhanced copper homeostasis in maize roots within acidic copper-contaminated soils ..... 1461

Multiscale Risks-Bioaccessibility Coupling Framework for Improving Derivation of Soil Cadmium Threshold ..... 1462

Restricting roles of arbuscular mycorrhizal fungi in cadmium uptake and translocation in rice ..... 1463

Tracing Cadmium Migration and Transformation from Atmospheric Deposition to Rice via Isotopic Fingerprinting ..... 1464

Soil-based assessment of lead release and contamination risks associated with lead-saturated biochars ..... 1465

Mechanism informed soil washing strategy for synchronized remediation of As, Cd, and Pb ..... 1466

Long-term organic fertilization reduces cadmium bioavailability via enhanced binding to organic fractions and Fe-bearing minerals ..... 1467

Arbuscular mycorrhiza orchestrates phenotypic plasticity of a critical suite of functional traits in plants under vanadium stress ..... 1468

Synergistic Remediation of Cadmium-Contaminated Soil and Antibiotic Resistance Gene Mitigation by Anaerobic Soil Biological Treatment ..... 1469

Eco-Restoration and Phytoremediation of Metal-Contaminated Soils in Arid Landscapes Using Mycorrhized Lygeum spartum ..... 1470

Predicting Continental-Scale Soil Mercury Concentrations in Australia to Refine Global Frameworks ..... 1471

## Session 305011: Novel Techniques in Molecular Environmental Soil Science .....1472

Sample preparation and characterize of soil dissolved organic matter ..... 1472

Influence of Soil Properties on the Extraction of Active Contaminant-Degrading Enzymes .....1473

Interaction mechanisms of Cr with organo-mineral complexes : Past achievements and future perspective .....1474

Iron, sulfur, and carbon dynamics collectively regulate the fate of cadmium over the sulfidation-reoxidation cycle .....1475

Visualization of Organic Carbon Distribution in Soil Minerals .....1476

Freeze-thaw driven colloid release from soils: Roles of aggregate turnover and pore network .....1477

Molecular Mechanism of Mn Oxides driven Oxidative Decomposition and Polymerization of Litter-Derived DOM at Different pH Revealed by FT-ICR MS ..... 1478

Elucidating the Molecular Mechanisms of Microplastics in Heavy Metal Transformation .....1479

Using an inexpensive RGB color sensor for field quantitative assessment of soil accessible Cu(II) .....1480

Solid Phase Molecular Diversity Enhances Soil Organic Matter Persistence ..... 1481

The Role of Molecular Environmental Science in Addressing a Changing Climate .....1482

Application of liquid chromatography coupled with FT-ICR MS for analysis of soil dissolved organic matter ..... 1483

**Session 305012: Soil Pollution and Remediation: Investigation, Mechanisms, and Remediation ..... 1484**

Enhanced Remediation of Herbicide-Contaminated Soils Using Phosphate-Modified Biochar ..... 1484

Interactions of selenium and heavy metals in paddy systems: Mechanisms and risk assessment ..... 1485

Model-based Rescue: Phytotoxicity Threshold and Control Strategy of Fluridone Residue on Herbicide-sensitive Rotation Maize ..... 1486

Methods for Assessment of Risk Posed to Agricultural Lands and Food Crops by PFAS-Contaminated Sludges and Irrigation Water ..... 1487

From Enrichment to Digestion: Risk–Benefit Evaluation of Selenium-Enriched Foods Under Arsenic Co-Exposure ..... 1488

Effects of Calcination Temperature on the Chemical Properties of Natural and Commercial Diatomites ..... 1489

Soil Cadmium Immobilization and Selenium Activation: A Strategy to Enhance Health in High Geological Background Areas ..... 1490

Arbuscular mycorrhizal fungi suffer from perfluorooctanoic acid in soil but ameliorate negative effects on plant performance ..... 1491

Engineering Iron–Microbe Interfaces on Biochar to Regulate Phosphate Fixation and Ibuprofen Retention across Soil–Water Continua ..... 1492

Occurrence and Transformation of Selenium and Cadmium in Porewater During Flood and Drainage: Implications for Safe Production of Rice in Cadmium-Contaminated Seleniferous Paddy Soils ..... 1493

Selenium-Based Rapid Health Risk Diagnosis and Green Remediation of Heavy Metal Pollution ..... 1494

In Situ Removal of Heavy Metals from Farmland Using Lignin Hydrogel-Based Nanocomposites: A Sustainable Strategy for Simultaneous Crop Production and Soil Remediation ..... 1495

Spatial Differentiation Pattern and Driving Mechanisms of Co-enrichment of Selenium and Cadmium in Soils from a Typical Indigenous Zinc Smelting Area ..... 1496

Cell-level Toxicological and Biodegradation Responses of Pure Bacterial Cultures to Per- and Polyfluoroalkyl Substances (PFAS) ..... 1497

Selenium Dynamics in Seleniferous Soils of Punjab: Role of Organic and Inorganic Amendments in Mitigating Selenium Toxicity ..... 1498

The potential role of groundwater microplastics on arsenic cycling in alluvial aquifers: insights from links of DOM characteristics and microbial community ..... 1499

Recent Strategies in Cadmium Translocation Control in Rice Plants: Mechanisms and Integrated Model ..... 1500

PFAS Composition in Irrigation Water Dictates PFAS Uptake by Lettuce: Evidenced by Field Sampling and Laboratory Simulation ..... 1501

Removal Performance and Mechanism of MOF-Based Iron-Carbon Composite Materials for PFOA and PFOS Electron Transfer Mediated by Iron Sites ..... 1502

Remediation of oxytetracycline-contaminated calcareous soil by a novel Zinc oxide/Schwertmannite composite: interface behavior and plant synergy ..... 1503

# 306 Salt-Affected Soils ..... 1504

## Session 306003: Understanding, Managing, and Innovating for Salt-Affected Soils ..... 1504

Digital Mapping for Spatial Prediction of Soil Properties Using Machine Learning Models for Soil Management in Rice Cultivation Areas Affected by Salt: A Case Study of Muang Phia, Ban Phai, Khon Kaen ..... 1504

Removal Mechanism and Process Application of Soil Washing Technology for Heavy Metals and Salt Ions in Contaminated Soil ..... 1505

Effects of Organic Materials on Nitrification Process in Saline-Alkali Farmland Soil . 1506

“Reshaping soil structure”: A systems engineering mode for ecological management of Salt-Affected Land ..... 1507

Reclamation of saline-alkali soils using fulvic acid: mechanisms and field effects ..... 1508

Salinity management when irrigating with non-conventional water sources ..... 1509

Enhancement of Organic Matter in Saline-Alkali Soils: Mechanisms and Technologies ..... 1510

Escaping Salinity, Cyclone and other Coastal Hazards for Crop Production through Early Sowing in Wet Soils with Strip Tillage ..... 1511

Sustainable Management of Saline and Sodic Black Soils in the Lowlands of Eastern Georgia ..... 1512

Quinoa as a Food Security Crop for Salt-affected and Dry Land Farming Systems ..... 1513

Identification of Salt-Tolerant Barley Genotypes Using Multiple Traits Index and Nutritional Performance at Early Growth Stages ..... 1514

Impact of neglected and underutilized species (NUS) on marginal lands: a potential tool for the recovery of soil functionality ..... 1515

Phosphorus Dynamics in Salt-Affected Drylands Soils: Influence of Parent Material and Agricultural Management ..... 1516

Managing saline soil to boost crop yield and halve nitrogen losses ..... 1517

Sustainability of Using Salt Affected Lands in Saline Agriculture ..... 1518

Hybrid CNN-LSTM Model for Predicting Nitrogen, Phosphorus, and Potassium (NPK) Fertilization Requirements: Integrating Satellite Spectral Indices with Field Microclimate Data ..... 1519

Synergistic Control of Soil Salinity via Ridge–Furrow Cultivation, Straw Mulching, and Mechanical Desalination in the Yellow River Delta ..... 1520

GeoAI-Informed Inversion: A Hierarchical Environmental Embedding Transformer (HEET) for Interpretable Soil Heavy Metal Mapping ..... 1521

Halophytes reclamation soil through improving soil structures, decreasing salinity and enhancing SOC storage in coastal saline land ..... 1522

Pedogenesis and classification of halomorphic soils in the Parnaíba Delta, Brazil ..... 1523

Soil salinization reduces belowground multifunctionality and crop yield at large spatial scale ..... 1524

Formation Mechanism of Salt Patches and Quantitative Relationship Between Water and Salt in Coastal Salinized Farmland ..... 1525

Coupling relationship between soil salinity, nutrients, and yield during reclaiming for planting rice in saline-sodic soils ..... 1526

Lab evaluation of the SoilVUE10 time domain reflectometry sensor under drying and wetting conditions of saline soils ..... 1527

The improvement of yield potential through amendment of saline-alkali soils in China: from plot to regional scales ..... 1528

Desalination of sabkha soils as potential source of strategic metals ..... 1529

Soil Nitrogen Transformation under Organic Residue Management in Salt-Affected Soils of the Vietnamese Mekong Delta ..... 1530

Spatial Synergies and Trade-offs between Soil Salinity and Organic Carbon in the Yellow River Delta ..... 1531

THE SPATIAL VARIATION OF SOIL QUALITY ACROSS LAND-USE AND DEPTH IN SALT-AFFECTED COASTAL SOILS: EVIDENCE FROM THE FORMER GO CONG DONG, VIETNAM ..... 1532

Spatial Distribution, Underlying Mechanisms, and Management Strategies of Soil Salinity in North China Cultivated land: A Soil Profile Perspective ..... 1533

Effects of Different Amendment Measures on the Properties of Coastal Saline-Alkali Soil and Cotton Growth in the Yellow River Delta ..... 1534

Aquaculture impoundment reduces salt leaching efficiency of subsurface drainage systems in neighboring farms ..... 1535

Effect of salinity on soil water vapor sorption and associated hysteresis ..... 1536

Integrating Hydrological Modeling and Explainable Machine Learning to Reveal the Key Drivers of Soil Salinization in the Huolin River Basin ..... 1537

Construction of an Integrated Improvement Technology Model of "Top Promotion, Middle Modification, and Bottom Drainage" for Severe Saline-Alkaline Land in Arid Areas ..... 1538

Determination of Irrigation Depth for Tomato considering the Cost for ..... 1539

Water under a Saline Condition ..... 1539

Bio-Organo Silicon Granules: A Strategy for Salinity Tolerance in Tomato ..... 1540

Saltwater intrusion impact on coastal agricultural soils of Los Lagos Region, Chile ... 1541

Mechanisms of Ammonia Volatilization Mitigation in Saline-Alkali Soils Amended with Biochar-Compost: Linking Reduced pH and Enhanced Aggregate Stability to Microbial Shifts ..... 1542

Optimal Groundwater Depth Thresholds for Sunflower in Salt-affected Farmland: A Process-Based Modeling Approach Across Hydrological Years in the Hetao Irrigation District ..... 1543

Application of biochar in saline soils enhances soil resilience and reduces greenhouse gas emissions in arid irrigation areas ..... 1544

The Construction of a Soil Profile Image Segmentation Dataset（SPISD） Based on Typical Soil Series Profile Photos from 13 Provinces in China ..... 1545

Advances in Amelioration Technologies for Sodic and Saline-Sodic Rice Paddy Fields with emphasis on the Songnen Plain of Northeast China ..... 1546

Rice Reclamation Activates Mineral Phosphorus and Alleviates Phosphorus Limitation in Saline-Alkali Soils ..... 1547

Synergistic Effect of the Compound Conditioner of Humic Acid, Zeolite and Phosphate Rock Powder on Soil Quality and Rice Yield of Coastal Saline Soil ..... 1548

Halophyte Salt Absorption Characteristics and Biological Remediation Pathways for Saline-Alkali Lands ..... 1549

Wenyao: A Domain-Specific Large Language Model for AI-Driven Saline–Alkali Land Reclamation ..... 1550

Future global salinization dynamics and their coupled driving mechanisms ..... 1551

Research on Salt-Alkali Tolerance Mechanisms of Characteristic Plants and Saline-Alkali Land Agriculture in Hetao-Ningxia Irrigation District ..... 1552

Effects and Mechanisms of Plant Growth-Promoting Bacteria in Enhancing Salt Tolerance of Soybean in Coastal Saline Soils ..... 1553

Identification of the dominant constraint factors in sodic saline-alkali paddy soils ..... 1554

Global Salt-affected Soils Crisis: FAO's Latest Report and Strategic Responses ..... 1555

Organic and inorganic carbon losses in straw amended saline and sodic soils ..... 1556

Biologically Driven Remediation of Saline–Alkali Soils Using Soil Bio-activation Technology in Arid Regions ..... 1557

# 307 Soils of Urban, Industrial, Traffic, Mining and Military Areas (SUITMA) ..... 1558

## Session 307001: Past, Present, and Future of SUITMA (Soils of Urban, Industrial, Traffic, Mining and Military Areas) ..... 1558

ON THE POSSIBILITIES OF USING NIR SPECTROSCOPY TO ESTABLISH THE GENETIC TYPE OF SOILS ..... 1558

Differentiation of Urban Lawn Soils on the Basis of a Combination of Physico-Chemical Methods(for Forensic Purposes) ..... 1559

Patterns of formation of the soil cover of historical urban parks (using the example of St. Petersburg, Russia) ..... 1560

Cultural layer in urban soils of Saint Petersburg, Russia ..... 1561

Carbon dioxide emissions from technogenic soils of the Central forest steppe ..... 1562

Urbanization Affects Soil Microbiome Profile Distribution in the Russian Arctic Region ..... 1563

Relationships between soil health and dynamics of soil potential pathogenic microbiota in functional domains of Xi'an urban greenspaces, China ..... 1564

Specific Features of Constructozems Functioning in Cities of the Steppe and Subtropical Zones of Southern Russia ..... 1565

Urban environmentally sensitive areas (U-ESA) in the city of Bratislava ..... 1566

Soil Diversity in the City of Moscow as a Mirror of Evolutionary Trends in Urban Pedogenesis. ..... 1567

Threshold sand content of sand-clay mixtures is affected by clay mineralogy and compaction effort ..... 1568

Hydrothermal Carbonization of Urban Organic Waste: Is it a sustainable pathway for soil restoration in highly urbanized regions? ..... 1569

Healthy Soils for Healthy Communities – A Community-based Urban Soil Initiative from Los Angeles ..... 1570

Do local non-statutory habitat designations reflect differences in below-ground biodiversity and functioning in urban green space? ..... 1571

Assessment of trace elements mobility in Technosols developed on heaps of historical polymetallic ore mining in the Sudety Mts., SW Poland ..... 1572

Who Bears the Burden? Trace Element Contamination and Environmental Justice in Chicago's Urban Parks ..... 1573

Challenges for SUITMA posed by the 2025–2034 Decade of Soil Sciences for Sustainable Development ..... 1574

Bioremediation of Explosive-Contaminated Soil at Military Sites: New Perspectives on Bioavailability and Ecotoxicological Effects ..... 1575

Urbanization Alters Soil Nutrients and Heavy Metals in Tropical Coastal Parks: A Case Study from Haikou, China ..... 1576

The Impact of urbanization on the physicochemical properties and microbial nutrient limitations of inland wetland soils ..... 1577

Urban soils mulching: temperature and moisture regulation in urban soils under different substrates ..... 1578

Environmental behavior of rare earth elements (REEs) in mining area: Occurrence, release, and transport ..... 1579

Characterization, hazards assessment and remediation of heavy metals-explosives contaminated soil in military training ranges ..... 1580

Phytoremediation Potential of Native Garden Plants in Urban Soil ..... 1581

Multidimensional approach to anthropogenic markers - evidence from urban soils in Krakow (SE Poland) ..... 1582

Urban Soils of Nanjing City ..... 1583

Urbanization Promotes Topsoil Black Carbon Accumulation: A Meta-analysis ..... 1584

Underestimation of soil organic carbon by global spatially explicit soil datasets in Chinese urban greenspaces ..... 1585

Upcycling Rare Earth Element Hyperaccumulator Biomass toward High-Performance Catalysts ..... 1586

Metabolic resilience of Allium cepa L. in urban technosols: the role of soil sealing and compaction on raffinose family oligosaccharides accumulation ..... 1587

Realising the value of urban soils ..... 1588

Effect of solar panel installation on past agricultural soils ..... 1589

# 308 Acid Sulphate Soils .....1590

## Session 308001: Health Maintenance and Sustainable Management of Acidified Soils .....1590

Humate Boosts Liming value? Insights into humate-assisted lime dissolution across acidic environments .....1590

The contribution of natural and anthropogenic causes to soil acidification rates under different fertilization practices and site conditions in southern China .....1591

Sensitivity of Soil Organic Matter Priming to Warming Depends on Diurnal Temperature Cycle .....1592

Biochar Mitigates the Kinetic Release of Aluminum from Soil Driven by Exogenous Acid .....1593

Diverse organic amendments mitigate soil acidification and enhance crop productivity in acid soil area over four decades .....1594

Co-application of lignosulfonate and calcium–magnesium phosphate fertilizer, an effective liming strategy for acidic purple soils in southwest China .....1595

Building a Stable Mineral–Microbial Buffering System for $Al^{3+}$ Detoxification and Productivity Recovery in Acidified Purple Soils .....1596

Microbial driven soil carbon cycling in red soil aggregates under different fertilization .....1597

Mycorrhiza-Mediated Soil Aggregate Stability under Maize//Soybean Intercropping in Acid Soil .....1598

Synergistic effects of Rice Straw-Pyrolyzed Biochar and Com-post on Acidity Mitigation and Carbon Sequestration in Acidic Soils: A Comparative Study .....1599

Mechanisms for Plants to Adapt to Toxicities of Aluminum and Manganese in Acidic Soil/Root Interfaces .....1600

Incorporating lime into acidic subsoil improved root growth and rhizosphere microbial activity in wheat .....1601

Spatio-temporal Variation Characteristics and Driving Mechanisms of Soil pH in Farmland of the Changbai Mountain–Liaodong Region .....1602

Acidification Discrepancy in Soils with Contrasting Surface Charge ..... 1603

Effect of Intermittent Irrigation on Rice Growth and GHG Emission in Rice Paddies on Acid Sulfate Soils ..... 1604

Liming regulates MAOC-POC trade-offs in paddy soils through a coupled mineral-microbial mechanism ..... 1605

Straw return exacerbates soil acidification in major Chinese croplands ..... 1606

Mechanisms of periphyton-induced carbonate precipitation and its role in regulating soil acidity in paddy soils ..... 1607

Synergistic Amelioration Effects of Dolomite-Based Composite Conditioner on Soil Acidification: Mechanisms and Long-Term Buffering Performance ..... 1608

Effect of straw incorporation on the formation of roots-surface iron plaque in rice and soil cadmium availability ..... 1609

Mechanisms of organic matter accumulation and pH buffering enhancement in Ultisol under long-term straw-derived amendments ..... 1610

Aluminum Toxicity is Key to Regulate Maize Yield in Ultisol under Different Nitrogen Fertilizer Treatments: A Long-Term Field Trial ..... 1611

Machine learning reveals that duration dominates rate in driving soil nitrogen cycling responses to long-term fertilization ..... 1612

The amelioration effects of different biomass and their derived biochars on acidified yellow cinnamon soil under equal raw material mass conditions ..... 1613

## Session 308002: Wetland Soils, Acid Sulfate Soils and Sulfidic Materials 1614

Differences in life history strategies of bacteria between paddy and upland soils and implications for carbon sequestration ..... 1614

Cross-regional transfer learning to predict acid sulfate soils in Finland using Random Forest ..... 1615

The Acid Sulfate Soil Distribution Mapping in The Buffer Area of Nusantara Capital City, Kalimantan, Indonesia ..... 1616

Coupling of microbial iron and sulfate reduction with organic carbon stabilization in mangrove soil ..... 1617

Coastal Acid Sulfate Soils and Their Mapping in Finland ..... 1618

The Effects of Pyrite on Soil Organic Carbon Storage in a Temperate Wetland Coastal Acid Sulfate Soil ..... 1619

Peat in Australia - Diversity, Values, Risks and the Universal Occurrence of Acid Sulfate Soils in South Australia ..... 1620

Neutralisation of Acid Sulfate Soils with Industrial Side Streams ..... 1621

Geophysical Methods for Mapping Acid Sulfate Soil Properties ..... 1622

Sulfur Geochemistry of a Sulfuric Wetland in Ostrobothnia, Western Finland ..... 1623

Improved sampling and laboratory methods using chip-trays for assessment and classification of acid sulfate soils ..... 1624

Iron oxyhydroxides, oxyhydroxysulfates and efflorescent sulfate salts as indicators of biogeochemical processes at low pH in acid sulfate weathering environments ..... 1625

# 309 Forest Soils ..... 1626

## Session 309001: Forest and Grassland Soil Functions and Sustainable Utilization under Global Change ..... 1626

Why the Effects of Vegetation Restoration on Soil Properties May Be Overestimated: Evidence from 30 Years of Long-Term Monitoring on the Loess Plateau, China ..... 1626

The regulation of microbial life-history strategies on soil carbon cycling ..... 1627

Heatwaves Increase Greenhouse Gas Emissions from Different Ecosystems ..... 1628

Coupling and decoupling of soil carbon, nitrogen, phosphorus and potassium stocks along a 6000 km northeast-southwest temperature gradient in China ..... 1629

Forest methane sink under climate change ..... 1630

Root exudate-mediated microbial gene activation drives phosphorus mobilization in mixed Chinese Fir species plantations ..... 1631

Phosphorus in (semi-)natural soils: concentration, stock, dynamics, and drivers ..... 1632

Effects of nitrogen deposition on plant community structure and niche characteristics in typical steppe ..... 1633

Grazing Modulates the Allelopathic Impact of an Invasive Shrub on Soil Seed Bank Diversity and Function: Implications for Grassland Soil Health ..... 1634

Study on the Influencing Mechanisms of Mercury Accumulation Characteristics in Grassland Soils of Guizhou Province Under the Context of Ecological Restoration ..... 1635

Characteristics of Serpentinite Soils in Northern Hokkaido ..... 1636

Influence of Forest Stand Age on Soil Water Dynamics in Semi-Arid Forests of the Loess Plateau ..... 1637

Southern urban forest converted from orchard abandonment: a potentially important $N_2O$ source driven by warm-humid climate ..... 1638

Tree functional diversity enhances forest carbon and nitrogen storage across gradients ..... 1639

Biochar mitigates the effects of nitrogen deposition on soil greenhouse gas emissions via microbial regulation in a subtropical forest ..... 1640

Soil-plant silicon cycle and climate change ..... 1641

Land-use change mediated associations among soil environmental factors, microbial networks, and soil multifunctionality: A case study of the Changchong River small watershed in Chaohu Lake ..... 1642

Soil organic carbon fraction mediated microbial community assembly along stand age and seasonal gradients in temperate poplar plantations ..... 1643

Microbial intra- and extracellular phosphorus recycling in response to global imbalanced soil nutrient changes ..... 1644

Soil Carbon and Soil Health Across a Prairie Restoration Chronosequence in Southern Wisconsin ..... 1645

Decadal Spatiotemporal Dynamics of Boreal Soil Chemistry in Response to Industrial Atmospheric Loading ..... 1646

## Session 309002: Forest Soil Management: Processes, Challenges, and Sustainable Production ..... 1647

Geographic variations and multiple drivers of soil organic carbon stability in larch plantations ..... 1647

Spatial Characteristics of Soil Organic Carbon in Forests of China ..... 1648

Mechanisms of soil organic carbon accumulation under green manure cover in citrus orchard ..... 1649

Fire-derived charcoal enhances soil ecological functions and recovery in subtropical forest plantations ..... 1650

Aggregate-mediated mechanisms of soil carbon and greenhouse gas emission under green manure cover in citrus orchard ..... 1651

Phosphorus Limitation and Adaptation Strategies for Productivity Formation of Pinus massoniana Plantations in China ..... 1652

Sensitivity of biochar-root interaction on the subtropical forest increase of sink and reduction of emission ..... 1653

Multi-trophic biodiversity regulates decomposition and mitigates drought effect ..... 1654

Managing Forest Soil Carbon to Preserve Climate and Biodiversity ..... 1655

Influence of species diversity and soil cementing substances on the stability of agglomerates in three forest types of Zhangguangcailing Mountains ..... 1656

Responses of selected soil physical properties to early stages of active ecological restoration in the Mistbelt forest of South Africa ..... 1657

Resistance and Resilience of Soil Microbial Communities to Forest Degradation and Their Role in Carbon Sequestration in Dry Tropical Forests ..... 1658

Burn history and residue solubility influence the transformation of pine litter in forest soils ..... 1659

Developmental plasticity drives convergent shifts in phosphorus acquisition strategies toward root phosphatase activity in Moso bamboo under nitrogen addition ..... 1660

Effects of different vegetation restoration measures on soil erosion resistance capacity on the typical watershed in the Three Gorges Reservoir Area ..... 1661

Cessation of nitrogen addition increased organic matter stability by decoupling carbon input and stabilization in a subtropical forest soil ..... 1662

The effects of N deposition on the decomposition of C rhizodeposits and its underlying microbial mechanism in Moso bamboo forest ..... 1663

The construction of core microbiota for phosphate-solubilizing and its regulation on phosphorus bioavailability in Moso bamboo rhizosphere ..... 1664

Compartmentalized Homeostasis Drives High Bamboo Forest Productivity Under Nutrient Imbalance ..... 1665

Plantation conversion of Eucalyptus promotes soil microbial necromass C accumulation ..... 1666

Afforestation improves soil multifunctionality through microbial activity and SOC molecular diversification ..... 1667

Soil Carbon Sequestration in forest soils: Limits and Potential versus Potential ..... 1668

Forest Development Determines the Compositions and Structures of Soil Invertebrate Communities in Reclaimed Coastal Lands ..... 1669

**Session 309004: Soil Microbial Diversity and Functions in Carbon and Nitrogen Cycling in Response to Tree Diversity, Wildfires and Climate Change ..... 1670**

Microbial Community Assembly, Network Resilience, and Nitrogen Functional Stability Under Canopy Gap Disturbance in Karst Forest Soils ..... 1670

Climate-driven shifts in microbe-mediated home field advantage in litter decomposition ..... 1671

Long-term throughfall exclusion decreased soil organic carbon components by higher soil CUE and lower microbial enzyme activities on Phyllostachys edulis ..... 1672

Forest plant community and fire control on soil microbial diversity and functions related to C and N cycling and GHG fluxes ..... 1673

Age-related shifts in soil microbial community structure and metabolic pathways in Picea schrenkiana var. Tianschanica plantations ..... 1674

Functional Sensitivity to Environmental Conditions Exceeds Community Composition in Forest Soils ..... 1675

Connecting Vegetation Biodiversity and Microbial Communities Role in Carbon Cycling Dynamics along a Post-Earthquake Vegetation Natural Restoration Sequences ..... 1676

The Resilience to Climate Change and Human Activities of the Forest Ecosystems in Central Africa, South America, Southeast Asia and European Union ..... 1677

Global wildfire effects on soil bacteriome and recovery trajectories ..... 1678

Nitrogen enrichment weakens tree diversity effects on productivity ..... 1680

MICROBIAL RECOLONIZATION DYNAMICSAND ECOLOGICAL SUCCESSION IN POST-FIRE SOILS ..... 1681

Soil depth outweighs environmental change in shaping microbial diversity–multifunctionality relationships ..... 1682

Effects of dead lying trunks of deciduous and coniferous trees on soil microbial communities in old-growth broadleaved forests after windthrows ..... 1683

Hidden Signals After the Flames: Integrating Soil Properties and Enzyme Dynamics in a Post-Fire Landscape ..... 1684

Shifts in soil microbial resource limitation along a natural gradient of ECM tree dominance in a subtropical montane forest ..... 1685

## Session 309005: Soil Organic Matter Dynamics and Nutrient Cycling in Global Forests under Climate Change ..... 1686

Winter Dynamics of Belowground Biophysical Processes in Two Temperate Forest Soils in Wisconsin, USA ..... 1686

Impacts of Mistletoe Infection on Soil Hydrology and Chemistry in Abies and Pinus Ecosystems ..... 1687

Subsequent Fire Alters Jack Pine Pyrogenic Organic Matter Persistence ..... 1688

The decomposition and stabilization of microbial residues in forest soil ..... 1689

Icelandic old birch woodlands have valuable soil carbon reserves ..... 1690

Ecological Stoichiometry of Plant-Soil Systems in Pinus sylvestris var. mongolica Plantations in the Semi-Arid Region of Northeast China ..... 1691

Land-use intensity restructures soil organic matter pools and stabilization pathways across forest–agriculture landscapes ..... 1692

Rubber-Based Agroforestry Ecosystems Enhance Soil Enzyme Activity but Exacerbate Microbial Nutrient Limitations ..... 1693

Temperature effects on nutrient biogeochemistry along a climosequence of forest soils in South Korea ..... 1694

Nature-based solutions for mitigating climate change: from rangelands to forests ..... 1695

Depth-resolved controls on phosphorus bioavailability across forest soil profiles in Northeast China ..... 1696

Deciphering the key role of core microbe in the decomposition of eucalyptus harvest residue ..... 1697

Global-Scale Land Use Change Will Become a Huge Potential Carbon “Source” in the Future: Mechanism Analysis and Spatial Projections to 2100 ..... 1698

Soil Organic Carbon Stocks and Controlling Factors in Planted and Natural Mangrove Forests Developed on Acid Sulfate Soils ..... 1699

Elevated $CO_2$ accelerates forest phosphorus cycling and alleviates fertilizer dependency ..... 1700

Optical Properties of Dissolved Organic Matter of Albic Retisols (Middle Taiga, Komi Republic, Russia) ..... 1701

Nitrogen deposition enhances microbial carbon pump-mediated soil organic carbon formation and stabilization ..... 1702

Contrasting effects of roots and arbuscular mycorrhizal fungi on soil carbon storage reveal divergent pathways in forest carbon cycling ..... 1703

Resilience of Mineral–Organic Carbon Interfaces Under Climate Extremes: Geochemical Controls on Soil Carbon Stability in Global Forests ..... 1704

Reduced below-ground carbon allocation triggers contrasting nitrogen dynamics in rhizosphere and bulk soil of alpine coniferous forests on the eastern Tibetan Plateau .. 1705

# 310 Paddy Soils ..... 1706

## Session 310002: Soil Health-Water-GHG Nexus for Sustainable Crop Production in Paddy Soils ..... 1706

Effect of Iron Materials on Methane Emission from Paddy Field ..... 1706

Effects of Alternate Wetting and Drying (AWD) on Driving Factors Controlling $CH_4$ Emissions from Rice Paddy Soils ..... 1707

Impact of Rising Tropospheric Ozone Concentrations on Rhizospheric Carbon Pools vis-à-vis Methane Emission in Tropical Rice Soil ..... 1708

Effect of dry direct-seeded and seedling-transplanted rice cultivation on methane emissions from a paddy field in Hokkaido, Japan. ..... 1709

The Effects of Paddy-Upland Rotation on the Six-Year Nitrogen Dynamics of $^{15}N$-labeled Cow Manure Compost ..... 1710

Utilization of Chemically Recycled Bio-based Plastic as Nitrogen Fertilizer in Paddy Soil: A Pot Culture Study for Brassica rapa ..... 1711

Potential for Rapid Improvement of Low-Fertility Soils by Cattle Manure Compost Application ..... 1712

Persistence and controls of soil organic carbon in paddy fields across Asian countries: a soil physicochemical fractionation approach ..... 1713

Decades of intensive rice cropping alter tropical soil fertility ..... 1714

Higher Efficiency of Nano-Sized Lime for Improved Limestone Conservation ..... 1715

Dry direct seeding rice and water saving irrigation reduce root exudation of organic acids and methane emission from paddy soils ..... 1716

Dual Benefits of Nano-Iron Oxide: Enhancing Rice Yield and Mitigating Greenhouse Gas Emissions Across Diverse Paddy Soils ..... 1717

Feasibility of Pot-Grown Seedling Transplanting as an Alternative Strategy to Mitigate CH4 Emissions and Enhance Rice Productivity in a Paddy Field ..... 1718

Transplanting Date Potentially Modulates Post-Season Methane Emissions via Residual Root Carbon Inputs in a Mono-Rice Paddy Field ..... 1719

Feeding the world while mitigating climate change: a global meta-synthesis of agronomic pathways for low-emission rice ..... 1720

Evaluating Rice Ratoon as a Novel Carbon Source and Identifying Growth-Regulating Factors in Mono-Rice Paddies in a Monsoon Region .....1721

Alternate Irrigation Reduces Methane Emissions in Malaysian Rice Paddies ..... 1722

Soil carbon budgets under three different fertilizer management in paddy fields, Japan. .....1723

Hybrid machine-learning and process-based regional crop modelling to improve rice production strategies in data-limited conditions: a case study of Lao PDR ..... 1724

Pedogenesis Shapes the Basis of Sustainability of Paddy Soils ..... 1725

Methane production potentials and methanogenic communities in winter-flooded rice paddy soils .....1726

Synergistic Effects of Water and Straw Management on Greenhouse Gas Dynamics and Carbon Sequestration in Subtropical Rice Ecosystems using Multichannel Automated Chamber System ..... 1727

Mechanisms of Rice Root Iron Plaque-Induced Greenhouse Gas Emissions in Paddy Soils .....1728

**Session 310004: Understanding Paddy Soil Microbiomes for Food and Climate Security ..... 1729**

Field investigation for 11 years revealed periodic fluctuations in the abundance and composition of bacterial and archaeal communities in paddy-upland rotational field .. 1729

Domesticated rice alters the rhizosphere microbiome, reducing nitrogen fixation and increasing nitrous oxide emissions ..... 1730

Denitrifier community responses to irrigation and straw management in subtropical paddy soils ..... 1731

Response of Rhizosphere Sulfur Utilization Microbiome to Rice Domestication ..... 1732

Rare earth elements reshape the methanotrophs community to enhance the $CH_4$ oxidation in paddy fields ..... 1733

Isolation, characterization and identification of culturable methane-oxidizing bacteria inhabiting paddy field ecosystem ..... 1734

Organic rice cultivation boosts microbial carbon use efficiency by modulating soil nutrient availability and microbial resource acquisition strategies ..... 1735

Coordinated Action of Firmicutes and Bacteroidetes in Rice Straw Decomposition .... 1736

Irrigation management drives the niche differentiation and metabolic versatility of ammonia-oxidizing archaea in paddy soils ..... 1737

Nitrogen fertilization increases rice productivity at the expense of endophytic bacterial community stability and diversity ..... 1738

Effects of nitrogen application on rhizosphere microorganisms, metabolites, and plant growth of rice under controlled irrigation in paddy fields ..... 1739

Synergistic Effects of Integrated Amendment Practices on Soil Health and Crop Productivity in a Newly Reclaimed Cultivated Land ..... 1740

Impact of microbial interactions on aerobic methanotrophs and methane oxidation activity in soils ..... 1741

From Genes to Gas: Dynamics of Active Methanogenic Food Webs in Rice Paddies .. 1742

The functional divergence and biogeographic patterns of electron-transferring flavoprotein (Etf) in paddy soil ..... 1743

Divergent Methanogenesis in Chinese Paddy Soils Driven by Organic Matter Composition under Climate Warming ..... 1744

Microbial background for mitigating methane emission from rice fields ..... 1745

Effects of light on microbial community in the surface soil of a paddy field .....1746

Beyond Nutrients: Minerals as Evolutionary Architects and Signaling Hubs in Soil Microbial Communities ..... 1747

Effective suppression of methane emission using ethephon and polymer mixture ..... 1748

Contrasting water regimes reshape anaerobic denitrification-primed organic nitrogen mineralization .....1749

Impact of land use and soil types on microbial $N_2O$ reduction potential mediated by nosZ communities .....1750

From DOM to Methane and Arsenic Release: Soil as a Key Control in Paddy Soils ... 1751

Discovery of iron-reducing diazotrophs in rice paddy soil and enhancement of nitrogen fixation by iron application .....1752

Nitrous oxide acts as an alternative electron acceptor for microbial methane oxidation in oxygen-deficient microcosms ..... 1753

The microbial community characteristics of soda saline-alkali paddy with flue gas desulfurization gypsum reclamation ..... 1754

Effects of rice-mushroom rotation systems on soil fungal communities and rice yield 1755

Rice root iron plaque as a mediator to enhance biological nitrogen fixation in paddy soil .....1756

## Session 310005: Multiple Paths to Soil Health: From Technology to Policy, From Paddy Fields to the Globe ..... 1757

Assessing Human Land Use Impacts on Soil Properties and Genesis in the Great Plains Region of the United States ..... 1757

Multitemporal Mapping of Soil Degradation to Support Environmental Restoration and Land-Use Planning in Minas Gerais, Brazil ..... 1758

Exploring the environmental feasibility of montmorillonite integration in the electrochemical oxidation of acid mine drainage ..... 1759

Methane Mitigation and Arsenic Immobilization in Paddy Soils by Sulfur-Containing Amendments Applied to Stimulate Sulfate-Reducing Bacteria ..... 1760

Reducing the Global Warming Potential of Rice Farming: Why Biochar Works Better than Compost ..... 1761

Cloud-Based Soil Erosion Drivers and Sediment Yield Assessment Using RUSLE–SDR Modeling in a Himalayan Watershed. ..... 1762

Changes in farm business model: Combined effects on soil health, ecosystem services, farm profit, and associated needs for incentives ..... 1763

Effect of autumn ratoon biomass on the rice growth and biomass during the following summer season under organic cultivation ..... 1764

Effects of fertilizers on arsenic accumulation in ratoon rice: implications for human health risks ..... 1765

Managing water and litter inputs to safeguard wetland soil health: coupled C-N-P responses to drying-rewetting in River Murray floodplain soils ..... 1766

Evaluating Cross-Regional Models for Predicting Soil Carbon and Properties in Taiwan Using Mid-Infrared Spectroscopy and Machine Learning ..... 1767

Integrated remediation strategies by health risk assessment of brown rice approaching technology for As, Cd, Cr, Ni, Cu and Zn-contaminated paddy soils in Taiwan ..... 1768

Effects of broiler litter and inorganic nitrogen on soil chemical indicators under varying row spacings in rainfed, no-till cotton systems ..... 1769

Rye–clover cover crop configuration (random vs alternating rows) with poultry litter: soil chemistry and cotton yield in Mississippi ..... 1770

Triangular approach (SQ-GQ-GY) based soil health assessment - A novel mechanism for ranking Resilient Rice Ecologies of eastern India ..... 1771

Biochar application improves soil health and tomato growth under drip irrigation in acidic soil ..... 1772

Enhancing soil health through organic amendments in an acid soil ..... 1773

The Potential of Returning Lignified Sesbania and Sun Hemp to the Soil to Increase Soil Organic Matter in Tropical Farmlands ..... 1774

Optimizing Water-saving Irrigation Strategies: Integrative Assessment of Soil Quality, Crop Yield, Greenhouse Gas Emissions, and Microbial Ecology in Rice Paddies ..... 1775

Changes in soil microbial community structure and carbon, nitrogen and sulfur functional genes under different cultivated land use patterns ..... 1776

Modified biochar enhances the growth of pepper and reduces the accumulation of cadmium in soil contaminated with cadmium ..... 1777

Organic amendments affect soil organic carbon and water-salt transport under subsurface drainage in a coastal reclamation area ..... 1778

Effects of subsurface drainage spacing and organic fertilizer application on water and salt transport characteristics of saline–alkali soil ..... 1779

Microbiome-enabled biochar tightens nitrogen cycling and boosts wheat water productivity under regulated deficit irrigation ..... 1780

Soil ridging combined with soil amendments regulates the arsenic-cadmium related geochemical cycles and mitigate its accumulation in rice ..... 1781

Impacts of Land Uses on Soil Quality in Western Patagonia ..... 1782

Water quality and sediment analysis at selected locations of Imo River, Imo State, In Southeastern Nigeria. ..... 1783

Agriculture as a strategy to improve the food – water – energy nexus in Atlantic Forest, Brazil ..... 1784

Microbial innovation for nitrogen management in paddy soil: A success story of Endophytic Azotobacter chroococuum MCC 3432 (NRRI-EndoN) ..... 1785

Effect of organic materials and sulfate addition on cadmium bioavailability and accumulation of rice in cadmium sulfide nanoparticles- and cadmium chloride-treated soil ..... 1786

Performance of sediment microbial fuel cells to inhibit arsenic availability in soil porewater: A laboratory study of three different Japanese paddy soils .....1787

Synergistic modulation of Zinc Bioavailability in Alluvial paddy soil: Integrating Zn-solubilizing microbial consortia, cow dung, and mineral Zinc fertilizers for sustainable Rice production in India .....1788

Earthworm burrows enhanced rice root growth under a no-tillage rice-rapeseed rotation system .....1789

# 401 Soils and the Environment / Soil Environment / Soil Ecology ..... 1790

## Session 401001: Peatlands in a Changing World ..... 1790

Carbon Storage Capacity of Peat Soils from High Bogs and Low Bogs ..... 1790

Human activities overrode natural climate controls on mercury deposition in Southern China during the late Holocene ..... 1791

Fungal biodiversity associated to alpine peatlands in northern Italy ..... 1792

The secret and fascinating world of the free-floating peat island of Posta Fibreno ..... 1793

Nutrient cycling in tropical peatland coconut agroecosystems integrating natural weeds as cover crops for sustainable management ..... 1794

Depth controls on $CO_2$ emissions from drained agricultural peat soils and implications for national greenhouse gas inventories ..... 1795

Breaking metabolomics limits for a molecular to pathway multidimensional analysis of metabolism alpine peatlands soil dissolved organic carbon ..... 1796

Alpine peatlands degradation drives soil organic carbon mineralization but improves stability ..... 1797

Soil nitrogen loss and altered plant nitrogen uptake following alpine peatland degradation: insights from nitrogen isotopes ..... 1798

Soil drying accelerates $CO_2$ emissions in global cold and wet ecosystems ..... 1799

Warming Amplifies Iron-Mediated Carbon Loss from Peatlands: A Positive Feedback Modulated By Soil Properties ..... 1800

## Session 401002: Soil Food Web Structure and Function under Global Change ..... 1801

Harnessing the soil food web for sustainable ecosystems: Current evidence and future perspectives ..... 1801

Coordinated plant-nematode ecological strategies shape soil carbon cycling ..... 1802

Soil β-Diversity responses to global change: mediated by assembly processes and multi-trophic interactions ..... 1803

Effects of livestock grazing intensity on ground-dwelling arthropod communities in a desert steppe in Inner Mongolia ..... 1804

Mechanism of soil fauna on soil microbial necromass carbon accumulation in a subtropical forest under nitrogen addition ..... 1805

Proteobacteria as keystone bridges in the micro-food web: a new strategy for biocontrol design ..... 1806

Impacts of chemical free turfgrass renovation on soil arthropod and nematode communities ..... 1807

Greater trophic diversity of soil animal communities under agricultural land use and tropical climate ..... 1808

Leaving deadwood in canopy gap mitigates the decline of soil multifunctioning ..... 1809

Legume Intercropping Reshapes Aggregate-Scale Soil Micro-Food Webs and Nutrient Regulation in Tropical Rubber Plantations ..... 1810

Multi-trophic interactions in the rhizosphere promote network complexity to synergize with root genetic programs for improve P acquisition in maize ..... 1811

Size-structured Energy Channeling in Soil Food Webs across Ecto- and Arbuscular Mycorrhiza-dominated Deciduous Forests ..... 1812

Drivers and Mechanisms of Biological Homogenization of Soil Protists in Human Land-Use Systems ..... 1813

Trophic interactions regulate the effects of long-term nitrogen enrichment on soil organic carbon ..... 1814

Testing the scaling effects and mechanisms of N-induced belowground biodiversity loss ..... 1815

The Effect of Soil Microorganisms on Organic Carbon Sequestration in Saline-Alkali Soils of the Hetao Irrigation District under Exogenous Organic Matter Addition ..... 1816

Pesticide contamination in agricultural soils in Shanghai: residual characteristics and ecological risks to soil biota ..... 1817

Effects of earthworms and their combined application with functional attractant on soil organic carbon dynamics: Regulation of organic carbon fractions, aggregate formation, and their carbon sequestration ..... 1818

Four decades of Soil Ecology: the good, the bad and the missing ..... 1819

Aggregate-Scale Microbial Communities: Spatial Heterogeneity, Potential food-webs & The Effect of Tillage ..... 1820

**Session 401003: Unveiling the Hidden World: Biodiversity and Ecological Function of Soil Fauna ..... 1821**

Investigating identification techniques and sample sizes effects on soil nematode community assessment ..... 1821

Fertilization Dictates Nematode-Microbe Trophic Interactions to Shape Plant Health and Soil Functions ..... 1822

Regulation of Soil Organic Carbon Fractions by Straw Return Duration via Microbial Community Shifts and Microbial Necromass Carbon ..... 1823

Enchytraeid Bioturbation as a Key Driver of Microplastic Redistribution in Soils ..... 1824

Grassland management and time jointly shape the gut microbiome of soil collembolan Folsomia candida: A laboratory study ..... 1825

Earthworm Responses to Veterinary Antibiotic Contamination in Soil and their Role in Mitigating Crop Toxicity ..... 1826

Stage-specific microbial dynamics underpin ecosystem restoration on tropical coral islands ..... 1827

Ecotoxicity of Combined Thallium and Polylactic Acid Microplastics Pollution on the Functional Traits of Folsomia candida ..... 1828

# 402 Soils, Food Security, and Human Health ..... 1829

## Session 402001: Conservation and Restoration of Black Soils in Agro-Ecosystems ..... 1829

Rice straw return by water-logged press-bury in autumn Enhanced Black Soils Carbon Stability in Northeast China Paddy Fields ..... 1829

Gully Growth Rates in Northeast China ..... 1830

Strip tillage combines the characteristics of conventional tillage and no-tillage in terms of soil macropore structure and hydrothermal conditions ..... 1831

Spatial Patterns of Ephemeral Gullies and Their Impacts on Farmland and Crop production in the Black Soil Region of Northeast China ..... 1832

Health regulation of black soil under the dual carbon strategy ..... 1833

Microbial-Mediated Mechanisms Underlying Soil Fertility Stability in the Northeast Black Soil Region of China ..... 1834

Black Soil Degradation in Northeast China and its Driving Factors ..... 1835

Spatial heterogeneity of soil C-N-P stoichiometry and its controlling factors in agricultural soils across the Songnen Plain, Northeast China ..... 1836

Multi-temporal monitoring of crop residue cover for large-scale classification of tillage practices: linking deep learning of UAV images with satellite-based spectral modelling ..... 1837

Effects of Furrow Straw Mulch on Soil Erosion and Organic Carbon Redistribution in Soil Aggregates at Sloping Farmland ..... 1838

Benchmark and Near-Benchmark Chernozems: Assessing Human-Induced Transformation and Pedodiversity for Black Soils Conservation ..... 1839

Organic Carbon Loss Process of Black Soil During Cultivation ..... 1840

Effects of incorporated straw length on runoff and soil loss from black soil under simulated heavy rainfall ..... 1841

Integrated Assessment of Slope Erosion in the Mollisol Region of Northeast China Using $^{137}Cs$ Tracing and Improved RUSLE2 model ..... 1842

Straw return combined with fertility enhances soil organic carbon and soil aggregate formation in Mollisol soils ..... 1843

Assessing Black Soil Health and Ecosystem Functioning Change in Response to Agricultural Practices in Foumbot, Western Cameroon ..... 1844

Long-Term No-tillage Retains Intact Biopores in the Topsoil Compared to Conventional Tillage Based on the Soil Profile Study ..... 1845

A Comprehensive Framework for Assessing Land Degradation Neutrality in Northeast China's Black Soil Region: Multi-Source Fusion, Driver Analysis, and Scenario Prediction ..... 1846

Interspecific interactions increase soil aggregate stability through altered root traits in long-term legume/maize intercropping ..... 1847

Effects of conservation tillage combined with diversified cropping on crop productivity and soil fertility in black soil region ..... 1848

The overlooked plant litter in the long-term biodiversity experiments ..... 1849

Soil Erosion Processes and Dynamic Mechanisms under Soil Compaction and Freeze-Thaw Cycles in the Black Soil Region of Northeast China ..... 1850

Intercropping, soil microbiomes, and mycotoxin risk: mechanistic pathways for safer maize production ..... 1851

Multi-platform monitoring method for the quality of Black soils cropland and site specific application ..... 1852

Mechanistic Insights into Cover Crops and Straw Incorporation: Root Traits, Soil Properties and Carbon Controls on Erosion Resistance across Degradation Gradients in Mollisols ..... 1853

Bio-tillage: A new perspective for sustainable agriculture ..... 1854

The impact of cover crops on the active components of organic carbon in black soil after straw return to the field ..... 1855

Carbon-rich African dark earths have lower carbon footprint than adjacent land use types ..... 1856

SynCom-Driven Iron Modulation Synergistically Controls Maize Root Rot ..... 1857

Mechanisms Underlying the Resistance of Rahnella sp. RS86 to Maize Root Rot ..... 1858

Soil fertility and mean annual precipitation regulate the influences of tillage regimes on black soil organic C stocks in Northeast China ..... 1859

Alleviating Soil Compaction under No-Till Management: Impacts of Cropping System ..... 1860

Thermal Stability of Soil Organic Matter in Farmland Chernozems ..... 1861

Short-term effects of overwintering on porosity of the compacted topsoil due to harvest traffic in Northeast China ..... 1862

Long-term no-tillage farming mitigates waterlogging during extreme rainfall events in black soil region of NE China ..... 1863

Drivers of soil quality and maize yield under long-term tillage and straw incorporation in Mollisols ..... 1864

Divergent Pathways of Soil Pore Structural Recovery under No-Till across a Semi-Arid to Semi-Humid Climatic Gradient ..... 1865

Coupling effects of freeze-thaw action and thawed soil depth on snowmelt erosion under near-surface hydrologic conditions in the Mollisol region of Northeast China ..... 1866

## Session 402004: Sustainable Management and Restoration of Black Soils: Global Experiences and Actions ..... 1867

Intensification tradeoff for crop yield under different tillage scenarios towards agricultural sustainability of Black Soils ..... 1867

ESTABLISHMENT OF A NATIONAL DIGITAL DATABASE AND INFORMATION SYSTEM FOR AGRICULTURAL SOILS IN MONGOLIA UNDER THE AFACI PROJECT ..... 1868

SOIL ORGANIC CARBON CHANGES UNDER LONG-TERM CULTIVATION IN MONGOLIAN KASTANOZEMS ..... 1869

Sambaquis as Records of Soil Management by Original Populations in the Holocene 1870

Degradation severity shifts environmental controls and vegetation effects on soil respiration in restored Mollisols ..... 1871

Comparative Study on Conservation and Utilization of Black Soils in China and Argentina ..... 1872

DSS for Sustainable Management and Conservation of Black Soils in Russia ..... 1873

Status of Black Soils in Rio de Janeiro: a legacy of mismanagement and recommended practices to reclaim their potential ..... 1874

Effects of Full Maize Straw returning on Soil Physical Properties and Maize Yield .... 1875

Assessment of the health of tropical black soils in the context of intensive agriculture: the case of the Vertisols of Tcheboa , Northern Cameroon ..... 1876

Assessing the nutrient potential and carbon stock of black soils in the Goma area (Eastern DRC) ..... 1877

Evaluating the Effectiveness of Conservation Tillage in the Black Soil Region of Northeast China Based on the Apparent Characteristics of Crop-Residue-Soil ..... 1878

Depth-dependent responses of soil microbial communities to subsoil tillage with straw enhance soil quality and crop yield ..... 1879

Sustainable Management and Restoration of Chernozem (Black Soil) in Vojvodina, the Republic of Serbia ..... 1880

Soil-landscape Modeling on Experimental Plots: RECSOIL on Black Soils in Central Russia ..... 1881

Assessment of water resources carrying capacity and identification of obstacle factors in the Songnen Plain based on a combined weighting-matter-element extension model .. 1882

Unveiling soil organic carbon sequestration potential and driving factors of global black soil: A meta-analysis ..... 1883

Uncovering the Biophysical Mitigation Potential of Off-Season Croplands across Global Black Soil Regions .....1884

The impact of conservation agriculture on functional microorganism-driven organic nitrogen mineralization and plant–microbe interactions in black soil regions ..... 1885

## Session 402005: Soil Security and Policy: Foundations for a Sustainable Future ..... 1886

Transferring Global Pedogenon Insights for Soil Security in Australia ..... 1886

Implementing the Soil Security Framework to Assess National Soil Governance: The Case of France ..... 1887

A soil security perspective: Reframing soil indicators for effective governance ..... 1888

A Pedogenon Approach to Delineating Soil Districts across Europe ..... 1889

A Decade of Soil Security: From Concept to Global Action ..... 1890

Quantifying Soil Security under Climate Change: Integrating Digital Soil Mapping and the Soil Security Assessment Framework ..... 1891

Legislation in Australia working for soil security (LAWSS) ..... 1892

Towards a Global Convention to Secure Soil ..... 1893

The Global Pedogenon Map: Combining and Spatialising the Factors of Soil Formation ..... 1894

Components of a national soil security strategy for sustainable soil use and management ..... 1895

European Union advances in soil protection with the Soil Monitoring Law, the Mission Soil and the Carbon farming ..... 1896

Connecting Soils and Consumers - The Regulation of Undefined Food Label Agricultural Sustainability Claims in Australia ..... 1897

Soil Genotype and Cultural Diversity in Jeju Island, Korea: Linking Soil Security with Societal Heritage ..... 1898

ADVOCATING FOR SOIL SECURITY: “FIRST CATCH YOUR HARE” ..... 1899

Development of a Canadian Soil Strategy ..... 1900

## Session 402006: Soil, Agriculture, and Human Futures: From Cold Frontiers to Global Challenges ..... 1901

Climate change intensifies phosphorus limitation in rice systems ..... 1901

Climate Change Effects on Rice Yield, Nutritional Health and the Free-Air $CO_2$ Enrichment Platform Innovation ..... 1902

From Soil to Grain: Organic Farming Improves Micronutrient Bioavailability ..... 1903

Mycobacterium vaccae: The Interconnection between Soil Health and Human Health 1904

Improving soil organic carbon sequestration through conservation tillage incorporating legume-based crop rotations ..... 1905

Managing domestic trade for food security with environmental and economic equity in China ..... 1906

Omics analysis reveals the antagonistic mechanism of foliar zinc-selenium application and its impact on wheat grain quality ..... 1907

Occurrence, Properties and Sustainable Management of Degraded Upland Soils Under a Changing Climate in the Philippines ..... 1908

Bio-Composts and Soil Microbiomes under a One Health Approach: Assessing Microbial Shifts and Antimicrobial Resistance in an Ex-Situ Pilot Study ..... 1909

Risks of Wheat Yields Reduction Under Future Climate Extremes ..... 1910

Towards Sustainable Rice Cropping Systems in a Changing Climate ..... 1911

Preservation of Patterned Ground in Permafrost Non-Affected Soils: Evidence form the Central Apennines (Italy) ..... 1912

The link between soil security and one health ..... 1913

Global wheat soil metagenomes reveal dryland cropping systems as microbial genomic hotspots ..... 1914

Optimizing Mineral Nutrition to Improve Soybean Yield and Quality under Elevated $CO_2$ ..... 1915

Characteristics of paddy soil: specifics in dynamics in organic carbon cycling ..... 1916

Deciphering the Role of Ethylene Signaling in Endoplasmic Reticulum Stress Response and Crop Resilience ..... 1917

Effects of Quinoa Cultivation on Greenhouse Gas Emissions and Soil Properties in Different Saline-Alkali Ecosystems ..... 1918

Revisiting Food Security in the Context of Climate Change: How Co-Occurring Heatwaves and Atmospheric Lead Deposition Jeopardize Crop Production ..... 1919

Low-Carbon Wheat Program: Integrating Soil Quality and Soil Carbon Dynamic into Life Cycle Assessment ..... 1920

Green recycling food waste management – a comparative case study in China ..... 1921

The compensation by elevated $CO_2$ for the impacts of warming yields a net positive overall effect of climate change on ecosystem services A global meta-analysis ..... 1922

Sustainable Management of Zinc in the Soil–Plant–Animal Continuum ..... 1923

Remediation of Degradaged Coastal Soil Using Biochar and Pyroligneous Acid ..... 1924

Beyond constant $CO_2$: Asymmetric day-night elevation, arbuscular mycorrhizal fungi, and intercropping dynamics shape plant physiology and productivity ..... 1925

The evolution of assimilable elements in the soil, and in the Sorrento Lemon PGI during growth ..... 1926

Integrated Physiological and Microbial Mechanisms Underlying Cold Tolerance in Japonica Rice: From Root Function to Rhizosphere Ecology ..... 1927

Abiotic Dephosphorylation of Nucleotides by Manganese oxides ..... 1928

Leveraging Sulfate to Modulate Arsenic Accumulation in Rice ..... 1929

Legacy soil information in the Northern Regions of Ghana: Implications for Integrated Soil Fertility Management (ISFM) ..... 1930

Soil Health-Driven Improvements in Tropical Fruit Production: Insights from a Vietnam "Living Lab" ..... 1931

Reduced Protein Content under Elevated $CO_2$ Enhances Perfluorooctanoic Acid Bioaccumulation in Wheat ..... 1932

Soil pH controls cropland $N_2O$ responses to rising $CO_2$ ..... 1933

Active soil microbiomes link urbanization and climate to zoonotic pathogen risk in Chinese cities ..... 1934

# 403 Soils and Land Use Change ..... 1935

## Session 403002: Land Use and Management Effects on Soil Health and Environmental Quality ..... 1935

Harnessing machine learning to improve nitrogen loss predictions in agroecosystems 1935

Soil health as a driver of yield patterns and management .....1936

Signatures of soil structural degradation: exploring stable water isotopes in soil pores 1937

Ecological impacts of farming practices on soil quality in a Mediterranean agroecosystem .....1938

Arenization in the Bauru Basin, Mato Grosso do Sul, Brazil ..... 1939

Evaluating the Impact of Stakeholder-Driven Agricultural Scenarios on Nitrogen Footprint and Virtual Nitrogen Factor using SWAT ..... 1940

Long-Term Land-Use Change in a Mediterranean Agroforestry System: Assessing and Restoring Soil Health in Apple Orchards of Pelion, Greece .....1941

Impact of organic mulch dose and type: A comprehensive Belgian case study .....1942

A Mixed-Methods Approach to Study Land Management and Soil Health in Urban Soils .....1943

Soil health in the vineyards of North-Western Italy: a story of terroirs .....1944

Innovating Truffle Agroforestry for Sustainable Mediterranean Landscapes: The TAIE Project ..... 1945

Impact of soil amendments, irrigation regimes, and subsurface drainage on wheat yield in coastal saline soils .....1946

Decoding the Rubik's Cube of Soil Health: A Genoform-Management-Phenoform Framework for Cropland in Northeast China ..... 1947

Effects of Land-use Variation on Soil Infiltration Capacity and Preferential Flow in Typical Low Hilly Area .....1948

Changes in salinity and vegetation growth under different land use types during the reclamation in coastal saline soil ..... 1949

Soil health and carbon sequestration dynamics in sandy soil within the Low Carbon Brazilian Beef protocol ..... 1950

Improving Soil Health in An Irrigated Arid Agroecosystem ..... 1951

Dynamic of soil organic carbon and phosphorus for different technological options in the Peruvian Amazon ..... 1952

Effects of straw returning method and irrigation lower limit on soil water and salt regulation and crop physiological characteristics in saline-alkali land of the Yellow River Delta ..... 1953

Effects of regenerative organic agriculture on soil quality and plant biochemistry .....1954

Post-Agrogenic Ecosystem Recovery in the Smolensk Lakeland: a Comprehensive Study in Western Russia ..... 1955

Impact of Intensive Vegetable Production on the Properties of Andisol ..... 1956

Scale-dependent mechanisms of grazing-induced soil carbon sequestration: Mediated by soil nitrogen quantity vs. heterogeneity in grasslands ..... 1957

Soil quality variation and its driving factors in rubber plantations of tropical China ....1958

Distribution of Available Phosphorus in the Soils of Belgrade Across Urban Development Zones ..... 1959

Rate of decomposition of litter fall and nutrients recycling in three soil use systems in the Peruvian Amazon ..... 1960

Tillage Intensity as a Driver of Soil Bacterial Composition and Functional Potential .. 1961

Soil health and ecosystem services across land uses and biogeographical regions in Europe ..... 1962

Decades of Data: Evaluating soil dynamics under contrasting tillage systems in Fuchsenbigl, Austria, since 1988 ..... 1963

Soil Health in U.S. Northern Great Plains Agriculture: A Comprehensive Review and Meta-Analysis ..... 1964

The nonlinear response effect of arable land quality on arable land fragmentation in mountain areas ..... 1965

Initial soil carbon status governs soil C stock changes, while pore characteristics improve after conversion of arable land to semi-natural grassland .....1966

SoilBio Reveals the Power of Forage Grasses to Improve Biological Functioning, Soil Health and Long-Term Soybean Yield in Maranhão, Brazil ..... 1967

Nitrogen dynamics, Soil Health, and Yield Responses under Long-Term Fertilizer and Manure Management in SAT of Central India ..... 1968

Biochar amendment mitigates negative effects of controlled irrigation on paddy soil structure: insights from micro-pore network analysis ..... 1969

Biochar application influenced soil quality in China's Loess Plateau ..... 1970

Effects of protection time and stationary state on the fractal dimensions characteristics of the sandy soil in Hunshandake Sandy Land ..... 1971

Long-Term No-Tillage Effects on Plant Residue Decomposition and Soil Organic Carbon Formation and Accumulation Patterns in a Japanese Andosol ..... 1972

Land Use and Management Effects on Soil Health of Three Soil Types in the Republic of Serbia ..... 1973

Multispecies pastures and the soil science dilemma ..... 1974

Four Decades of Soil Organic Carbon Dynamics in Seasonally Flooded Haor Wetlands of Northeastern Bangladesh amid Landscape Transformation ..... 1975

Vegetation-Driven Soil Organic Carbon Regulate Mercury Accumulation in Karst Soil Profiles ..... 1976

THE LEGISLATIVE BASIS FOR SOIL PROTECTION – THE RED SOIL BOOK .. 1977

Soil Physical and Chemical Responses Along a Pasture-to-Forest Succession in the Alps ..... 1978

Replacing periodic burning with improved forages reshapes soil carbon and nitrogen dynamics and tree–soil interactions in Colombian savannas. ..... 1979

The effect of winter-sown oat catch crops on nitrogen leaching after livestock grazing ..... 1980

Effects of Different Land Use Types on Soil–Microbial Ecochemical Stoichiometry in Agro-Pastoral Ecotones ..... 1981

Iceland’s degradation history is taking a hopeful turn through revegetation and ecosystem monitoring ..... 1982

Century-long spatiotemporal variation in cropland soil erosion and the roles of anthropogenic factors in the Tuojiang River Basin, China ..... 1983

Soil Properties of Oil Palm Based Agroforestry System ..... 1984

Aggregate-Size-Specific Carbon and Nitrogen Responses to Reduced and Deep Tillage in Japanese Andosols ..... 1985

Soil carbon and nitrogen dynamics in mechanized maize-based intercropping ..... 1986

Enhancing soil-wheat resilience with biochar-based microbial fertilizer application under deficit irrigation ..... 1987

Microbiome-enabled biochar mitigates drought impacts and improves soil nutrient availability and maize growth in under deficit irrigation ..... 1988

The effect of organic farming systems and cover crops on soil health after land use change in southeastern USA ..... 1989

Oil Palm Height, Frond Development and Chlorophyll Responses under Monoculture and Nauclea subdita Agroforestry ..... 1990

Regional scale mapping of a soil health index using machine learning and digital soil mapping with driver attribution ..... 1991

Transformation patterns of precipitation-soil water-crop water in karst regions and their impact on maize yield ..... 1992

Decision support tool for improved nutrient and carbon management at farm level .... 1993

Optimized fertilization strengthens the soil health–yield relationship by enhancing biological activities ..... 1994

Grassland legacy effects regulate nutrient leaching losses in cropland phases in long-term grassland-crop rotations ..... 1995

Assessing Nutrient Status of Selected Lowland Rice Soils in Siniloan, Laguna, Philippines ..... 1996

Synergistic Effects of Irrigation Regimes and Duckweed Species on Microplastic Dynamics in Paddy soil ..... 1997

Organic slow-release nitrogen fertilizer affects soil organic carbon sequestration, greenhouse gas emission, and rice yields under water-saving irrigation ..... 1998

# 404 Soil Education and Public Awareness / Soil Science Education ..... 1999

## Session 404002: Share Our Standpoints of Soil Teaching and Learning at School, University and Civil Society for the Future Development of Better Soil Education System ..... 1999

Soil Science Education in Kazakhstan Universities: Strengthening Soil and Geological Literacy for Sustainable Land Management ..... 1999

The World Soil of the Year: a way to promote and popularize soils ..... 2000

Current Status and Future Trends of Soil Education in Mongolia ..... 2001

Making Darcy visible: A simple apparatus for teaching Saturated Flow in Soil ..... 2002

Deciphering Soils through the Power of Games ..... 2003

The Soil Health Indicator: A Scalable, Rapid Assessment Tool Linking Soil Science to Agricultural Sustainability ..... 2122

Assessment and Long-Term Monitoring of Soil Quality in France and its Overseas Territories ..... 2123

Building a Grower Facing Portal for Soil Health Assessment and Decision Making ... 2124

A Comparison of Two Soil Health Assessment Frameworks ..... 2125

The role of SOILS4MED project in promoting soil information in the Mediterranean and a unique case study from Apulia Region in Italy. ..... 2126

## Session 408002: Nature-Based Solutions for Soil Health and Sustainable Crop Production ..... 2127

Nature-based Solutions for Transforming Smallholder Agriculture in Highland Areas of Northern Thailand ..... 2127

Application of Dredged Soil Resource Utilization in Mangrove Habitat Improvement 2128

Cover Crop-Driven Anaerobic Soil Disinfestation Enhances Weed Suppression and Collard Greens Productivity ..... 2129

Changes in Soil Bacterial and Fungal Community Characteristics in Response to Biochar Treatments ..... 2130

Productive Grassland: Influence of Mixture Composition on Yield and Nitrogen Response Efficiency in a Temperate Region ..... 2131

Synergistic Mitigation of Crop Rhizosphere Soil Microbial Nitrogen Limitation by Maize-Peanut Intercropping and Straw Return in Black Soil Region: Insights from Extracellular Enzyme Stoichiometry ..... 2132

Assessing rhizosphere and root traits of maize varieties under drought in integrated greenhouse and field experiments ..... 2133

BIOCHAR AND COMPOST AS NATURE-POSITIVE SOLUTIONS TO SEMI-ARID AGRICULTURE: MULTI-LEVEL ASSESSMENTS OF SOIL HEALTH, NUTRIENT CYCLING, AND GREENHOUSE GAS EMISSIONS ..... 2134

Synergistic Water Retention and Growth Promotion Mechanism of Tamarind Seed Polysaccharide-Sodium Alginate-PGPRs Hydrogel in Dry-hot Valley Areas ..... 2135

Connection between fertilizer inputs, soil microbiota and common bean agronomic performance ..... 2136

Effect of Biogenic Synthesized Nano Sulphur on growth, yield and quality of Soybean ..... 2137

Enhancing Drought and Salinity Resilience in Tomato Plants Using Plant Growth-Promoting Bacillus Species from Semi-Arid Soils of Australia ..... 2138

Optimizing Soil Health in Tropical Peatlands through Coconut-based Agroforestry ..... 2139

Ecological Regulation Function of Soil Microorganisms: Synergistic Effects of Arbuscular Mycorrhizal Fungi and Trichoderma in Biotic and Abiotic Stress Tolerance ..... 2140

Identification of Bioplastic-associated Bacteria with Potential Degradative Activity in an Agricultural Soil System ..... 2141

Soil health responses to nature-positive management regulate soil water infiltration in semi-arid agroecosystems ..... 2142

Restoring Soil Health and Managing Soilborne Pathogens in Vietnam's Intensified Coffee and Black Pepper Systems ..... 2143

Field evaluation of biochar on soil and crops in Northern Ireland (NI). ..... 2144

Faba bean-wheat intercropping sustains soil water and nutrient cycling, and the carbon availability for microbes in the short term. ..... 2145

Evaluation of the soil quality improvement potential through basalt rock dust amendment ..... 2146

Comparison study on soil layer disturbance between vertical rotary tillage and horizontal rotary tillage ..... 2147

Identification of soil health-related problems in apple orchards: preliminary results from the Grójec Living Lab ..... 2148

Ecosystem service value of conservation tillage with cover crop-maize intercropping in the northeast black land of China ..... 2149

Agronomic constraints limit the climate change mitigation potential of winter cover crops in Europe ..... 2150

Enhancement of soil physical properties through the use of cover crops: A systematic review for the Argentinean Pampas ..... 2151

Soil Natural Productivity: A Path to Self-Regeneration and Sustainability — Empirical Insights from Hechuren's "Natural Mulching and No-Tillage" ..... 2152

Structured Mini-Dunes (SMDs): Engineered Soil Structures for Moisture Retention and Salinity Control in Arid Sabkha Soils ..... 2153

Soil-crop-fertilization interactions drive the effects of Fusarium oxysporum FO12 on soil properties and plant nutrition ..... 2154

Microbial activity and biomass in a cultivated and bioinoculated soil under water and nutritional deficit conditions ..... 2155

Cover Copping for Soil Health Improvement in North-western Canada ..... 2156

Maize/peanut intercropping advantages: evidence for soil biota-mediated nitrogen transfer ..... 2157

Microbial solutions for reducing soil nitrous oxide emissions ..... 2158

Intercropping increases soil multifunctionality potentially by increasing the abundance of functional genes: evidence from a long-term field experiment ..... 2159

Phytoremediation Potential of Native Plant Species for Improving Soil Health in Vineyards with High Levels of Arsenic and Copper ..... 2160

Copper–Amendment Interactions Drive Molecular and Physiological Stress Responses in Vitis vinifera ..... 2161

What matters to detect early soil health change in integrated cover crop systems? ..... 2162

## Session 408003: Soil Management Practices on Soil Health in Plastic Greenhouses ..... 2163

Farming system diversification enhances land use efficiency of China's protected horticulture ..... 2163

Balancing Crop Yield and Environmental Risk in Chinese Greenhouse Vegetable Production Systems: Insights from Phosphorus Management ..... 2164

High nitrogen-use efficiency cabbage varieties deliver a win-win of enhanced yield and reduced nitrogen discharges: comprehensive evaluation and field validation ..... 2165

Dose-Dependent Effects of Biochar on Physiological Metabolism and Fruit Quality in Tomatoes ..... 2166

Microplastics Engineer Denitrification Hotspots in the Plastisphere to Drive Soil $N_2O$ Emissions ..... 2167

Mechanisms of nitrate accumulation in solar greenhouse with long-term high nitrogen inputs in the Loess Plateau of China ..... 2168

Dynamics of soil salinization and its combined effect with nutrients on the microbial community in solar greenhouses ..... 2169

Organic fertilizer improves soil carbon sequestration via macroaggregate formation in intensively vegetable cultivation system ..... 2170

Enhanced soil ecosystem multifunctionality and microbial community shifts following spent mushroom substrate application in protected vineyards ..... 2171

Enhancing silicon uptake and use efficiency in Piper nigrum L. against Fusarium disease on acidic soils using Calciprill and sodium silicate ..... 2172

Biochar-based microbial fertilizer enhances cucumber growth and yield by improving soil quality in protected agriculture ..... 2173

Organic substitution as a soil health management practice alleviates salinization and steers nematode assembly in plastic greenhouse soils ..... 2174

## Session 408004: Soil & Environmental Health: Advancing Science for Human & Ecosystem Resilience ..... 2175

Cadmium Uptake by Maize Grown with Microplastics and Their Effect on Water Content and Grain Quality ..... 2175

Strategies to reduce cadmium and arsenic accumulation in rice to protect human health ..... 2176

Ecological and Human Health Risks of Heavy Metals in Coastal Sediments of Grand Bahama Island ..... 2177

A seminal paper, 25 years on: enrichment factors cited rather than understood ..... 2178

Oral Exposure of Arsenic-Contaminated Soils Triggers Hepatic Ferroptosis via Iron Dysregulation and Glutathione Metabolism Disruption: From Bioavailability to Mechanisms ..... 2179

Particle and mass characteristics influence in vitro and in vivo lead bioavailability from multiple sources ..... 2180

Green Remediation Theory and Technological Application for Heavy Metal-Polluted Farmland Soils — Chinese Practices and Experience ..... 2181

Revisiting Cr Risk in Paddies: Colloidal Cr Formation and Its Mechanistic Impacts on Rice Uptake ..... 2182

Mercury sources in soil of forest ecosystems and health risks to birds ..... 2183

Dietary strategies to reduce bioavailability and toxicity of lead, cadmium, and arsenic following oral exposure: Mechanisms and health implications ..... 2184

Agricultural Water Reuse: Effects on Soil and Ecosystem Health ..... 2185

Harnessing Non-Conventional Salt-Accumulating Plants for Integrated Phytodesalination and Sustainable Salinity Management ..... 2186

Hyphospheric Phosphorus Enhances Arsenic Hyperaccumulation in Pteris vittata via Coordinated Mycorrhizal and Root Uptake Pathways ..... 2187

Arsenic-hyperaccumulator Pteris vittata effectively uses sparingly-soluble phosphate rock: Rhizosphere solubilization, nutrient improvement, and As accumulation ..... 2188

Luxury at a Cost: Linking Portable XRF-Based Bioaccessible Chromium to ICP-MS-Determined Chromate and Dermal Permeation Risk in Bright-colored Leather Products ..... 2189

Soil health mediates diversification effects on crop resilience in tropical agroecosystems ..... 2190

Multi-dimensional Drivers for Urban Soil Microbial Diversity: Insights from the Species-area Relationship ..... 2191

Health risk assessment of dietary cadmium exposure based on cadmium bioavailability in food: opportunities and challenges ..... 2192

How Does Vegetation Cover Alter Mercury Accumulation and Mobility in Soils of Guizhou? ..... 2193

Calcium in Soil Health: Beyond pH Management to Mitigating Phosphorus Overuse and Enhancing Carbon Stabilization ..... 2194

Biochar laced with elemental sulfur restores microbial function in aridland soils ..... 2195

Variation in Arsenic Accumulation and Remediation Potential among Different Genotypes of Pteris vittata ..... 2196

Sustainability of mountainous olive orchards: evaluation of soil microbial diversity and functionality of organic, integrated and conventional agroecosystems. ..... 2197

Seeing is believing: Exploring metal interactions in rice paddies using chemical imaging tools ..... 2198

Heavy metals migration from soil to animal/human in heavy metal contaminated areas: Fate and risk of legacy Pb and Cd ..... 2199

Divergent Responses of Topsoil and Subsoil Microbial Communities to Cadmium Stress in a Wastewater-Irrigated Farmland ..... 2200

From Predict to Control Cr(VI) Risk in Agricultural Soil: Aging Model and S-nZVI Stabilization for Crop Safety ..... 2201

PFAS in Agro-Food Systems: Risk Management Strategies ..... 2202

Phosphorus and cover crop management practices alter phosphorus speciation in soils and eroded sediments ..... 2203

Recruitment of copiotrophic and autotrophic bacteria by hyperaccumulators enhances nutrient cycling to reclaim degraded soils at abandoned rare earth elements mining sites ..... 2204

Metabolic flexibility of rhizobacteria drives soil nutrient cycling and enhances rare earth elements hyperaccumulation in ferns colonizing degraded mine ecosystems ..... 2205

Mechanistic Study of Rare Earth Element Bioleaching Mediated by Komagataeibacter xylinus ..... 2206

Effects of different nitrogen fertilizer types on the remediation efficiency of Pteris vittata in arsenic-contaminated soil ..... 2207

Multi-Pathway Synergy Drives Rapid Soil Fertility and Crop Yield Improvement in Newly Reclaimed Cropland: The Role of Integrated Soil Improvement ..... 2208

Qualidade e saúde do solo: bases para a transição agroecológica em agroecossistemas ..... 2209

Phytate-Mediated Arsenic Hyperaccumulation in Pteris vittata: Synthesis, Sequestration, and Exudation ..... 2210

Soil quality in a long-term Tifton 85 pasture overseeded with forage radish and annual ryegrass ..... 2211

Re-thinking Climate Resilience in Smallholder Agriculture: Insights from Technology, Economics, and Policy Interactions in Eastern India ..... 2212

Adapting to Climate Change: Sustaining Soil Health through Carbon-Nitrogen Cycle Management ..... 2213

Reinventing Soil Health in the Plastic Age: Fungal-Nano Synergies for Microplastic Remediation ..... 2214

Digital Characterization of the Spatial Distribution of the Albic Horizon in the Northeast Black Soil Region ..... 2215

# 409 Carbon Neutrality and Global Change ..... 2216

## Session 409001: Advances in Best Management Practices for Achieving Climate-Smart Agriculture ..... 2216

EcoPond: A Nature-Based Solution to Reduce Methane Emissions from Animal Effluent and Manure Storage Systems ..... 2216

Effect of cover crops on carbon and nitrogen stocks in perennial crops under Mediterranean conditions ..... 2217

Optimizing sampling protocols for agriculture and soil science: introduction of a spatial machine learning decision support tool ..... 2218

Pathways to resilience in dryland agricultural systems ..... 2219

Impacts of Corn Hybrid and Fertilization Strategies on Plant Carbon Allocation and Soil Carbon Dynamics Under Variable Moisture Conditions ..... 2220

Innovative Pasture Diversification Trials to Enhance Soil Health, Carbon Dynamics, and Climate Resilience ..... 2221

Does a long-term no-till corn-soybean rotation decrease nitrous oxide emissions in Alfisols? ..... 2222

Neglecting Non-Rainfall Water Contributions Results in an Overestimation of Crop Water Use Efficiency ..... 2223

Soil Carbon Cycle and Carbon Sequestration Strategies in Saline-Alkali fields ..... 2224

Interactive effects of straw and biochar amendments on soil organic carbon stabilization and bacterial community dynamics ..... 2225

Short rotation coppice on degraded and fertile soils ..... 2226

Effects of combined application of biochar and manure composts on greenhouse gas emissions and forage maize yields ..... 2227

Determining acid neutralization capacity of crushed basalt during enhanced rock weathering in soil ..... 2228

Greenhouse gas emissions as influenced by integrated conservation management practices under organic production in a sandy soil ..... 2229

Can Perennials Cut Nitrous Oxide Emissions? Insights from Manitoba Cropping Systems ..... 2230

A Spatially-Explicit Framework for Agricultural Best Management Practices: Guidelines, Database, and Future Directions ..... 2231

Mechanism of soil carbon sequestration in cover cropping systems ..... 2232

Adopting wheat-legume intercropping enhances crop productivity and soil quality: Evidence from living labs across Pakistan under LEGUMINOSE Project ..... 2233

Towards a low-carbon and climate-resilient Mediterranean agriculture: the integration of Conservation Agriculture and 4R Nutrient Stewardship in herbaceous and woody crops ..... 2234

Enhancing Soil Resilience and Climate Adaptation through Site-Specific Agroecological Strategies - AGROSUS Project ..... 2235

Nitrogen use for improved profitability and sustainability of rice production in central Myanmar ..... 2236

Sustainable Pathways for Southeast Asia's Rice Systems ..... 2237

Functional legume rotations optimize global synergies between soil organic carbon accrual and crop yield ..... 2238

Influence of soil pH and cover crop residues on the abundance of ammonia oxidizing microorganisms and nitrous oxide emissions in tropical agriculture soils ..... 2239

Effects of Plant Density, Nitrogen Rate and Supplemental Irrigation on Maize Source-Sink Relationship and Water-Nitrogen Use Efficiency Under Straw Mulch in Northeast China ..... 2240

Effects of manure and agronomic practices on particulate, dissolved, and mineral-associated organic matter in a long-term integrated crop-livestock system ..... 2241

Soil Organic Carbon Buffers Wheat Yield Against Warming by Regulating Phenological Sensitivity ..... 2242

Decadal biochar legacy alters soil physicochemical properties but not microbial C turnover ..... 2243

Root-zone Water and Salt Transport Dynamics and Irrigation Optimization in Mulched Drip-Irrigated Cotton Fields in Arid Regions ..... 2244

Evaluating BMPs that reduce Greenhouse gas emissions ($N_2O$) and improve water quality: A case study in southern Ontario, Canada ..... 2245

Silvopastoral Systems as a Strategy to Increase Carbon Stocks and Improve Soil Health in Brazilian Drylands ..... 2246

Including water-salinity stress hysteresis and compensation to empirical root water uptake models ..... 2247

Regional variation in the potential to reach net zero emissions in global agriculture ... 2248

Optimizing soil improvement and nitrogen management for sustainable crop production .....2249

Controlled-Release Fertilizers in BMPs for Sustainable Agriculture ..... 2250

## Session 409002: Advancing Soil Organic Carbon Science for Sustainable Land Management ..... 2251

Comprehensive Review: Insights into the Dynamics of Soil Organic Carbon Stocks in Vineyards ..... 2251

Optimal Selection of Soil Organic Carbon Prediction Models and Their Implications for Potential Soil Erosion Estimation Using the Revised Universal Soil Loss Equation in Southern Chinese Counties ..... 2252

Whole-profile soil organic carbon simulation in China using SOILcarb model ..... 2253

Coupled geomorphic and climate-driven biogeochemical processes regulate soil organic carbon stocks in agricultural terraces ..... 2254

Modelling climate change impacts on soil organic carbon dynamics in dryland croplands ..... 2255

Divergent drivers of soil organic carbon factions across global pedoclimatic zones .... 2256

Cover crop species and mixtures drive contrasting vertical distribution of root- and residue-derived C and N in conservation-tilled sandy Ultisols ..... 2257

Crushed basalt application shows soil improvement and potential carbon capture in wheat field ..... 2258

Soil organic carbon buffers crop yields against climate extremes ..... 2259

Mapping soil organic carbon across China using ensemble modelling at 30 m spatial resolution ..... 2260

Deep soil carbon accrual by perennial energy crops offers large potential for atmospheric $CO_2$ removal ..... 2261

Soil Organic Carbon Assessment Across Land-Use and Management Scenarios in a Metropolitan Urban–Rural Territory ..... 2262

Advancing soil organic carbon assessment by integrating fractionated pools, biology, and land-use history across managed landscapes ..... 2263

Global estimation of soil microbial-derived carbon stocks and its implications for the carbon cycle ..... 2264

Soil vertical gradients shape soil respiration but not its temperature sensitivity ..... 2265

Is the tobacco carbon footprint influenced by soil attributes? ..... 2266

Counteracting warming-induced soil organic matter loss via cyanobacteria- enhanced glomalin-mediated aggregation ..... 2267

Land use change and management strategies promoting soil organic carbon sequestration in LAC countries ..... 2268

Quantifying non-linear relationships and causal effects of soil organic carbon on crop productivity stability ..... 2269

Integrating Remote Sensing and Process-Based Modeling to Assess Grassland Soil Organic Carbon Change ..... 2270

National Scale Mapping of Soil Organic Carbon Vulnerability Indicators in New Zealand ..... 2271

Unraveling the Interconnections of Soil Organic Carbon Dynamics in Sustainable Land Management ..... 2272

Response of soil organic carbon to the changes in plant productivity under warming ..... 2273

Vegetation restoration of degraded meadows by non-dominant species decreased cumulative $CO_2$ emissions and temperature sensitivity of soil respiration rates ..... 2274

Refining the RothC Model's Decomposition Rate Modifier for Moisture to Improve Soil Organic Carbon Estimation in Paddy Fields ..... 2275

Urban soils carbon across the scales and regions: who and what drive the spatio-temporal variability of soil carbon in urban areas ..... 2276

Depth Variations and Drivers of Soil Organic Carbon in Croplands of the Black Soil Region, Northeast China ..... 2277

Assessing pedotransfer functions for bulk density to improve predictions of soil carbon stocks in Retisols (Moscow region, boreal zone) ..... 2278

Depth-resolved soil organic carbon estimation: a scalable approach ..... 2279

## Session 409003: Climate Change and Soil Microbial Control Carbon Sequestration ..... 2280

Aridity-driven soil carbon vulnerability to drought shapes future carbon–climate feedbacks ..... 2280

Rotational grazing with no-till can efficiently maintain soil carbon stocks in Mediterranean woody pastures but results in lower microbial abundance and fungal diversity than grazing abandonment ..... 2281

Soil carbon mineralization decreased in desert steppe by light grazing but not fencing management ..... 2282

Grazing disturbance reduces soil organic carbon sequestration and stability in desert steppe ..... 2283

Mechanism of increased drought intensity stimulating the extracellular polymeric substance (EPS) accumulation and their contribution to soil organic carbon ..... 2284

Microplastics from conventional and biodegradable mulch films alter microbial necromass accumulation and organic carbon sequestration ..... 2285

Shifts in C-degradation genes and microbial metabolic activity with vegetation types affected the surface soil organic carbon pool ..... 2286

Drivers and Consequences of Microbial-Derived Carbon Loss in Degraded Alpine Grasslands on the Qinghai-Xizang Plateau ..... 2287

Fungal Necromass Carbon: Insights into Global Soil Carbon Sequestration and Its Practical Implementation in Circular Agricultural Systems ..... 2288

The influence and mechanism of the interaction between Mineral-associated Organic Carbon and soil aggregates on soil carbon sequestration ..... 2289

Orchard soils exhibit the highest microbial $CO_2$ fixation potential and contribution to soil organic carbon across land-use types in Qaidam Basin ..... 2290

Community, metabolic pathways and fixation potential of soil $CO_2$-fixing microorganisms on the Loess Plateau ..... 2291

Linking the diversity of soil $CO_2$-fixing microorganisms with soil organic carbon accumulation along biological soil crust chronosequence ..... 2292

Stability of Soil Organic Carbon and Shifts in Microbial Community Structure along Vegetation Succession in the Shrinking Area of Plateau Inland Lake ..... 2293

Quantifying microbial controls on particulate and mineral-associated organic matter in cropland soils ..... 2294

Activation Energy of Soil Organic Matter Decomposition and Consequences of Global Warming ..... 2295

Microbial Intracellular Carbon Storage: A Missing Link in Global Soil Carbon Sequestration Framework ..... 2296

Grassland degradation-induced soil organic carbon loss associated with micro-food web simplification ..... 2297

Long-term fate of photosynthetic carbon in desert plants: microbial necromass-driven pathways for soil carbon stabilization ..... 2298

Role of microbial-derived carbon to soil organic carbon formation during natural and artificial vegetation restoration ..... 2299

Exploring drivers of microbial drought sensitivity through combined laboratory and field approaches ..... 2300

Global Change Reshapes Microbial Residues and Plant Lignin Components in Soils . 2301

Turnover of microbial biomass residues to soil organic matter and its contribution mechanism ..... 2302

Stoichiometric steering of microbial necromass–mineral coupling drives Technosol genesis in iron mine tailings ..... 2303

Mechanisms underlying rhizosphere regulation of soil organic carbon components and stability by leguminous plants in subtropical karst and non-karst forests ..... 2304

Soil organic carbon formation from plant and microbial residual carbon: Effects of home-ffeld advantage and root litter quality ..... 2305

Warming alters fresh-carbon assimilating bacterial community relevant to priming effect in Mollisols ..... 2306

Microbial Interactions as a Primary Regulator of Soil Organic Carbon Age ..... 2307

From incubations to landscapes: compensatory thermal adaptation and substrate effects constrain microbial carbon processing in forest soils across China ..... 2308

Coupled temperature sensitivity of microbial carbon and nitrogen use efficiencies in forest soils on a continental scale ..... 2309

Microbially Constructed Carbon–Mineral–Structural Interfaces: Revealing a Novel Perspective on Soil Texture–Mediated Organic Carbon Temperature Sensitivity .....2310

Divergent responses of plant lignin phenols and microbial residues to global change: a global meta-analysis .....2311

Symbiosis in an asymmetrical day-night high-$CO_2$ world: Interactive effects of arbuscular mycorrhizal fungi and elevated $CO_2$ on legume nutrition and soil fertility .....2312

Global warming decreased soil organic carbon stock via increasing organic matter lability and heterotrophic respiration ..... 2313

Decades of no-till coupled with warming improves topsoil soil organic matter accrual via stimulate microbial carbon use efficiency .....2314

Context-dependent dominance of plant detritus or microbial necromass in soil organic carbon accrual ..... 2315

Thermal acclimation of soil microbial respiration across permafrost ecosystems: contrasting roles of autotrophic and heterotrophic microorganisms .....2316

Effects of warming on soil organic carbon ..... 2317

Recognizing the role of soil microorganisms in organic carbon accumulation in drylands .....2318

**Session 409004: Evolution of Soil Organic Matter: Impacts of Climate Change and Land Use Change ..... 2319**

Reconstruction of Rhizosphere Soil Microenvironments: Synergistic Plant-Microbe Purification Mechanisms and Practices ..... 2319

Soil Microbial Diversity and Carbon Stability for Climate Resilient Land Management in the Western Ghats ..... 2320

Differences of Soil Carbon Sequestration Efficiency of Typical Cropland in China, UK and USA ..... 2321

To reduce $CH_4$ and $N_2O$ emissions whilst maintaining crop yield in rice-wheat system in China with climate change using SPACSYS model ..... 2322

Does elevated atmosphere $CO_2$ facilitate soil carbon sequestration? ..... 2323

Soil Carbon Change under Land Use and Climate Change ..... 2324

Spatial variation and agronomic impacts of inherent soil productivity on wheat in China ..... 2325

Integration of artificial intelligence and remote sensing reflectance spectra for regional SOC Mapping ..... 2326

Decadal extreme drought reduces alpine subsoil carbon stocks ..... 2327

Crop diversification as a climate-smart strategy: A model-based assessment in Mediterranean orchards for soil carbon sequestration and greenhouse gas emissions mitigation ..... 2328

Mechanisms of low carbon sequestration efficiency in the croplands of the eastern Loess Plateau ..... 2329

Photocatalytic generation of reactive oxygen species from dissolved black carbon: Identification of photoproduction sites ..... 2330

Long-Term Organic Fertilization Enhances Particulate Organic Matter Accumulation through Macroaggregate Formation in the Loess Plateau ..... 2331

Organic amendments differentially regulate POC and MAOC dynamics in topsoil and subsoil ..... 2332

A systematic analysis and review of soil organic carbon stocks in urban greenspaces . 2333

Nitrogen addition effects on soil organic carbon accrual in cropland land ..... 2334

Quantifying soil organic matter effects on nitrogen use efficiency and fate in wheat-maize cropping systems: a $^{15}N$ tracer approach ..... 2335

Phosphorus as the key driver: Long-term fertilization unlocks nonlinear gains in nitrogen recovery efficiency in Chinese croplands ..... 2336

Organic fertilization under conservation tillage enhances biopore formation and particulate organic matter accumulation via fraction-specific pore relationships in a Vertisol ..... 2337

Simulation of the evolution of cropland soil organic carbon in the Tuojiang River Basin over the past century ..... 2338

Fertilizer-N recovery links to SOC stabilization and fractionation in straw-mulched soil: Insights from $^{15}N$-tracing and $^{13}C$ natural abundance ..... 2339

Mechanisms of soil organic carbon sequestration within aggregates of black soil under long-term land use change ..... 2340

Contrasting effects of long-term fertilization on pore structure and POM in upland and paddy soils revealed by X-ray CT ..... 2341

Socioeconomic development and cropland projects reversed soil carbon loss across the whole cropland profile: Evidence from China ..... 2342

Microbial necromass outperforms the chemical stability of SOC in predicting soil multifunctionality under 44-year of organic amendment in red paddy soil ..... 2343

Straw-decomposing inoculants strengthen the mitigation effect of straw on $N_2O$ emissions via synergistically inhibiting the abundance and activity of AOB in a wheat field ..... 2344

Evolutionary Characteristics of Stable Organic Matter in Lateritic Red Soils under Long-Term Rotation and Fertilization Systems ..... 2345

Nitrogen fertilization enhances straw carbon sequestration in reclaimed mine soils by regulating microbial community stability and function ..... 2346

Distribution Characteristics and Influencing Factors of Carbon and Nitrogen Content in Mineral-Associated Organic Matter in Mollisols (Phaeozems) of Northeast China ..... 2347

Long-term organic farming alters soil organic matter molecular composition through divergent microbial processing pathways ..... 2348

Spatiotemporal Spectral Reconstruction for Soil Organic Matter Mapping under Complex Cropland Surface Conditions ..... 2349

Long-term Grassland Conversion Reshapes Deep Soil C and N Cycling: Thermodynamic Destabilization and Microbial Drivers ..... 2350

## Session 409006: One Carbon Metabolism in Terrestrial Ecosystems .....2351

Optimizing and simulating the soil carbon fractions within the BEPS-MEND framework .....2351

Exploring Aerobic Methanotroph Diversity in Terrestrial Habitats: Recent Advances and Challenges for Further Studies .....2352

Ozone-driven spatial divergence of methane production in rice paddies ..... 2353

Life under Limiting Methane Metabolic Flexibility, Hydrogen Use, and Starvation/Revival of Methylocystis spp. ..... 2354

Temperature-Driven Virus-Host Interactions Regulating Methane Production in Paddy Fields .....2355

Combined Effects of Elevated Ozone and Warming on Methanogenesis in Paddy Soil Across Depths ..... 2356

Combined Effects of Elevated Ozone and Straw Return on Plant-Soil-Microbial Mechanisms Regulating Paddy Methane Emissions ..... 2357

Microbial-Driven Humification of Sugarcane Leaf Residues in Lateritic Soils .....2358

Vertical profiles of community and activity of methanotrophs in large lake and reservoir of Southwest China ..... 2359

Elevational patterns and temperature sensitivity of soil methane oxidation in southeastern Tibetan forests .....2360

Functional Diversity and Interactions of CO-utilizing Microbial Communities ..... 2361

Culturing the Uncultured Anaerobes from the Perspective of Microbial Growth Curves .....2362

The overlooked methanogenic N2-fixation revealed during rice straw incorporation by metatranscriptomics ..... 2363

Mechanistic insights of manganese-resistant bacteria in enhancing heavy metal phytoremediation by Koelreuteria paniculata .....2364

## Session 409007: Physical, Chemical, and Biological Drivers for Soil Greenhouse Gas Fluxes ..... 2365

A “naturally dominant” chemo-denitrification pathway drives $N_2O$ emissions in Tibetan glacier retreat zones ..... 2365

Understanding methane emission dynamics in temperate rice fields through systematic review and statistical modeling ..... 2366

Carbon Dioxide Emissions from Soil Can Serve as a Sustainable Characteristic of the Forest-Steppe Biome ..... 2367

Agricultural Management and Soil Leakiness: Drivers of Methane Oxidation and Nitrification ..... 2368

Soil greenhouse gas emissions under different land uses across Europe ..... 2369

Greenhouse Gas Emissions from Soils and Ways to Reduce Them ..... 2370

Recent stabilization of agricultural non-$CO_2$ greenhouse gas emissions in China ..... 2371

Rainfall-induced hot moments of $N_2O$ emissions in sandy agricultural soils managed with winter cover crops ..... 2372

Global Response and Mechanism of Methane Cycling in Wetlands Under Elevated Atmospheric $CO_2$ and Warming ..... 2373

$CO_2$ fixation by soil algae in agricultural lands ..... 2374

Effect of no-tillage based cover crop management on greenhouse gas emissions, and greenhouse gas balance in organic soybean field in Hokkaido, Japan ..... 2375

Coupling expression of nitrifying and denitrifying genes induce high $N_2O$ emissions in strong ammonia oxidizing soils ..... 2376

Effects of Elevated $CO_2$ Concentrations and Temperature on Soil Inorganic Nitrogen and Greenhouse Gas Emissions in Winter Wheat ..... 2377

Evaluation of Greenhouse Gas Emission Characteristics by the Use of Organic Resources and No-Tillings in Organic Agricultural-Based Corn Plantations ..... 2378

$N_2O$ fluxes after application of organic and mineral fertilizers to acidic tea soils in Kenya ..... 2379

Microbial phosphorus cycling: A key driver of $CO_2$ emission in phosphorus-supplied subtropical forest soils ..... 2380

The Carbon-Iron Coupling Mechanism of Organic Carbon Turnover in the Rice Root Zone Under Redox Gradients ..... 2381

Effect of soil structure on $N_2O$ production and emission ..... 2382

Coupling of nocturnal water vapor and $CO_2$ uptake in arid soils: Comparative analysis from three arid soils ..... 2383

Carbon Flux Responses of Rice Paddy to Coupled Heatwaves and Droughts in the Jianghan Plain ..... 2384

No tillage reduces nitrous oxide emissions in Winter and early Spring globally ..... 2385

Organic amendments regulated the pattern and product stoichiometry of nitrate reduction processes in arable soils ..... 2386

Root Exudate Chemistry Drives Divergent Carbon Fates in Rice Paddies ..... 2387

Contrasting warming responses of anaerobic microbial communities explain variation in methane Q10 across paddy soils ..... 2388

Slowing down the strong ammonia oxidation is the key to reduce $N_2O$ emission in alkaline agricultural soils ..... 2389

Effects of three differently activated biochars on greenhouse gas emissions from a fertile clay loam in boreal conditions ..... 2390

Inhibition and the mechanisms of ethene on methanogen ..... 2391

Static Chamber Protocol Optimization for Soil Greenhouse Gas Flux Measurements under Pulse Events ..... 2392

Microbial regulation of soil $CO_2$ and $CH_4$ emissions during rewetting of degraded peatlands ..... 2393

Effect of soil structure on $CO_2$ production and emission ..... 2394

Belowground Cross-trophic Networks Impact $CH_4$ and $CO_2$ Emissions in Degraded Alpine Peatlands ..... 2395

Soil carbon quality modulates the responses of soil respiration and its heterotrophic and autotrophic components to fertilization under straw return and extreme rainfall ..... 2396

Effects of Three-Dimensional Surface Area Correction on Soil $CO_2$ Flux and Biomass Accounting in a Gully Landscape ..... 2397

Mechanistic controls of nitrous oxide emissions revealed by flux-gradient measurements and site-specific incubations ..... 2398

Iron-carbon coupling mechanisms during soil organic carbon dynamics under climate-change conditions in long-term biochar-amended soils ..... 2399

**Session 409008: Soil Carbon Dynamics and Impacts of Land Use and Management ...2400**

Slope aspect regulates constrained soil organic carbon dynamics under long-term grazing exclusion in semiarid grasslands ....2400

Divergent carbon stabilisation pathways in Australian soils ....2401

Biologically driven short-term inorganic carbon changes in calcareous soils ....2402

Carbon-Nitrogen Dynamics and Soil Aggregation in Terrace Soil of Rice-Wheat Cropping System ....2403

Soil C and N storages response to land-use and management changes: A comparison of various plant-soil ecosystems in Eastern Japan .... 2404

Cover crop quantity and quality jointly drive priming effects and new soil organic carbon formation across soil fertilization histories ....2405

Root exudates-mediated rhizosphere microbiome participate in carbon fixation along the chronosequence ....2406

Chemical Composition of Soil Organic Carbon and Its Relationship with Soil Properties and Carbon Dynamics in Tropical Soils of Thailand ....2407

Synergistic Relationships Between Soil Organic and Inorganic Carbon in North China's Croplands: A Mini-review and Prospective .... 2408

Organic Amendments Enhance the Formation of both Organic and Inorganic Carbon in Macroaggregates of Cropland in the North China Plain ....2409

Coupling mechanism of soil organic carbon and inorganic carbon ....2410

Global response of soil organic carbon pools to land management and climate change2411

The conversion of paddy to upland soils triggers the loss of soil organic carbon stocks by promoting Fe oxide crystallization .... 2412

Management's Role in Loss of Color and Organic Carbon in Great Plain Soils of the United States .... 2413

Nitrification-induced acidity controls $CO_2$ emission from soil carbonates .... 2414

The Impact of Soil Heterogeneity on Organic Carbon Mineralization ....2415

Global warming potential in rice paddy soil applied with different fertilization and tillage management .... 2416

Soil Carbon-Nitrogen Pools in Different Land Use Types and Varying Time Scales: Implications for Soil Health and Sustainable Agriculture ..... 2417

Soil Acidification in the Anthropocene ..... 2418

Impact of Land Use and Windbreak Establishment on Soil Carbon Pools in Dryland Agroecosystems ..... 2419

Effects of alley cover crops on soil carbon and nitrogen along the soil profile in almond orchards under a Mediterranean climate ..... 2420

Linking the Chemical Composition of Soil Organic Carbon with the Formation, Stability, and Carbon Accumulation of Soil Aggregates under Divergent Land Uses ..... 2421

Soil carbon stocks and sequestration rates in Northern Irish grasslands ..... 2422

A Large Carbon Stock in Global Coarse Woody Debris and Its Contribution to Soil Carbon Dynamics ..... 2423

Soil Calcium Carbonate Leaching Process of Millennial Soil Chronosequence in Coastal Regions ..... 2424

Biochar-loaded NH+ 4-N effectively reduces carbon emissions by changing the composition of soil organic carbon and microbial community ..... 2425

Contrasting microbial C dynamics under different long-term P fertilization regimes in non-allophanic Andosols. ..... 2426

Soil Carbon Storage Enhances Nitrogen Fixation by Accumulating Necromass-Bound Micronutrients ..... 2427

Long-Term Variability of Peat Soil Properties and $CO_2$ Flux in a Planted Forest Ecosystem ..... 2428

Regulating soil organic–inorganic carbon trade-offs through integrated nitrogen and organic fertilization ..... 2429

Effects of Eucalyptus robusta afforestation on soil carbon fractions and the underlying mechanisms ..... 2430

Impact of burning cessation on soil carbon stocks and organic matter fractions in semi-natural grasslands ..... 2431

Soil microbiomes exhibit threshold responses to oxygen isotope enrichment ..... 2432

Spatial variations of organic matter concent in cultivated land topsoil in North China based on updated soil databases ..... 2433

Digging Deeper: Increasing Precision in quantifying Soil Organic Carbon Losses After Forest-to-Cultivated Land Conversion ..... 2434

Long-term impact of integrated crop-livestock-forest systems on soil organic carbon sequestration and edaphic health in the Brazil ..... 2435

Vulnerable Zone of Soil Inorganic Carbon Loss in Intensive Agricultural Regions ..... 2436

Using Natural $\delta^{13}C$ Signature from Both Soil Profiles and Topsoils to Understand Organic Carbon Transformation in Mollisols (Phaeozems) of Northeast China ..... 2437

Soil carbon dynamics and microbial associations across the soil profile under regenerative management in Northern California vineyards ..... 2438

Temporal Dynamics of Soil Organic Carbon Fractions and Microbial Activity Across a Chronosequence of Abandoned Paddy Fields in Korea ..... 2439

Impact of Blast Furnace Slag-Based Enhanced Rock Weathering Alters Soil Organic Carbon Dynamics through Microbial Activity ..... 2440

Initial organic carbon content controls the depth-dependent soil organic carbon responses to liming ..... 2441

Trade-offs between soil organic carbon input and mineralization driven by high-level phosphorus fertilization: 30-year field evidence ..... 2442

Soil organic carbon stocks under no-tillage on farms in European Russia ..... 2443

Effects of Historical Land Use Changes on Deep Soil Carbon, Nitrogen and Microbial Communities in Alpine Sandy Region ..... 2444

Modeling of carbon sequestration in future climate conditions in a long-term field experiment on light-textured Retisol in the Tver Region, Russia ..... 2445

Effects of 50-year long-term land-use and management changes on soil C and N stocks and their stable isotope ratios at the Yamagata University Farm, Japan ..... 2446

Chemical carbon sequestration dominates leguminous green manure return, whereas physical carbon sequestration prevails in non-leguminous systems ..... 2447

Beyond Methane: Reassessing the Role of Rice Paddies in Global Warming ..... 2448

Tree proximity effects on soil organic carbon, bulk density and soil moisture in a dryland landscape ..... 2449

Land use effects on soil carbon retention through glomalin-mediated aggregation ..... 2450

Demonstration and application of zero-carbon Taoyuan biochar carbon sequestration technology ..... 2451

## Session 409009: Soil Carbon Fluxes for Climate and Soil Health .....2452

A model-based tool for supporting sustainable management of soil organic carbon in Swiss croplands .....2452

Effects of tillage practices on environment, energy, and economy of maize production in Northeast China .....2453

Exogenous organic carbon-induced stoichiometric balance stimulates microbial high growth potential yield strategies to promote necromass accumulation in soil carbon pools .....2454

Management practices to mitigate long-term soil organic carbon losses in temperate arable soils .....2455

Integrated carbon-nitrogen budget and cost-effective management in China ..... 2456

Blue Carbon Stocks in Brazilian Mangroves .....2457

Mangrove Biomass and Soil Carbon Stocks: Spatial Approach in the Cananéia Region .....2458

Soil carbon fluxes as indicator of Healthy urban soils in a Mediterranean city ..... 2459

Effects of crop rotation and organic amendments on crop productivity, soil chemical properties, and soil organic carbon accumulation in greenhouse vegetable systems .... 2460

Permafrost ecosystems of Pur-Taz interfluve (Western Siberia) as a source of methane in the context of climate change .....2461

How temperature controls methane fluxes and methanogenic pathways at polygonal tundra of Samoylov Island in the Lena River Delta (Northern Siberia) ..... 2462

Contrasting effects of inorganic vs. organic nitrogen deposition on soil respiration: Evidence from a 10-year field experiment .....2463

Mechanisms and Mitigation Potential for Carbon Sequestration and Greenhouse Gas Emissions in Paddy Soils under Climate Change ..... 2464

Global Distribution Patterns of Phytolith-Occluded Carbon in Terrestrial Ecosystems Based on Meta-Analysis and Machine Learning ..... 2465

Divergent but coupled responses of soil organic and inorganic carbon to .....2466

global warming and aridity ..... 2466

$CO_2$ emission following total vegetation removal: a pilot study ..... 2467

Greenhouse Gas Fluxes and Their Environmental Drivers in a Coastal Peatland of the Kamchatka Peninsula ..... 2468

Decoupling the "Pump" and the "Tomb": Depth-Dependent Soil Organic Carbon Stabilization Mechanisms under Long-Term Conservation Tillage ..... 2469

A Mechanistic–AI and Remote-Sensing Assimilation Framework to Quantify Straw-Return Impacts on Soil Carbon Fluxes and Soil Health ..... 2470

Evaluating global soil carbon sequestration and loss: an expert assessment of their role in climate mitigation and adaptation ..... 2471

Integrating Soil Properties and Management into Data-Driven Modeling of Soil $CO_2$Efflux in Urban Green Roofs ..... 2472

Monitoring Soil Carbon Storage and Soil Respiration in Street-Level Green Infrastructure ..... 2473

Soil Carbon Fluxes in Agroecosystems with Annual and Perennial Grasses in the Moscow region of Russia ..... 2474

Drivers and Spatial Variability of $CO_2$ Efflux in Agrosilvopastoral System and Native Vegetation in the Brazilian Cerrado ..... 2475

The permanence of carbon sequestration in agricultural soil – what do we (not) know 2476

Soil Organic Carbon: A Key Player for Fertility, Climate, and Healthy Land ..... 2477

Linking Seasonal Controls and Biological Degradation in the Chihuahuan Desert, Mexico ..... 2478

Impact of Integrated Agricultural Systems on Soil $CO_2$ Efflux in the Cerrado Biome . 2479

## Session 409010: Soil Microbial Life and Death: Impacts on Soil Organic Carbon Dynamics Under Global Change ..... 2480

Unlocking Carbon Management Sustainability by Quantifying Microbial Necromass and SOC Asynchrony ..... 2480

Global viral auxiliary metabolic genes drive carbon sequestration under climate change ..... 2481

Multi-Scale Evidence for Declining Microbial Carbon Fixation Along Forest Succession Gradients ..... 2482

Synergistic regulation of dissolved organic matter and microbial communities on microbial necromass accumulation under long-term organic material application ..... 2483

Patterns and drivers of soil microbial residue carbon responses to precipitation changes in grassland ecosystems ..... 2484

Regulation of soil aggregate stability and carbon sequestration by microorganisms under long-term nitrogen and phosphorus application ..... 2485

Effect of pH Gradient on Microbial Respiration using an Artificial Soil Systems ..... 2486

Differential impacts of moisture fluctuation on dissolved organic matter under different water availability by regulating bacterial network and functional structure ..... 2487

Changing from divergence to convergence between soil microbial communities derived from intracellular and extracellular DNAs along a hydrothermal gradient on the Tibetan Plateau ..... 2488

Soil microbial community structure and soil carbon dynamics in fields and hedgerows of Northern Irish Grasslands ..... 2489

Time-scale dependent responses of microbial carbon use efficiency to warming in alpine soils on the Qinghai-Tibetan Plateau ..... 2490

Fenton reaction facilitates chitin degradation and nitrogen acquisition in the ectomycorrhizal fungus Suillus luteus ..... 2491

Soil microbial life-history strategies covary with ecosystem multifunctionality across aridity gradients ..... 2492

Resolving the microbial processes underpinning necromass pools across landuses ..... 2493

Microbial sequestration pathways of soil organic carbon in meadow steppes under long-term nitrogen and phosphorus application: Analysis based on aggregate scale residual carbon ..... 2494

Viral mediation of microbial turnover governs soil organic matter allocation ..... 2495

Protist predation shifts bacterial life strategies and increases carbon use efficiency across contrasting soils ..... 2496

Clay-organic matter interactions drive microbial necromass preservation in soils ..... 2497

Soil organic matter persistence emerges from recursive microbial necromass and mineral feedbacks ..... 2498

Urban soil virus homogenization reshapes microbial organic matter decomposition and carbon sequestration potential ..... 2499

Microbial Enhancement of Soil Inorganic Carbon and Its Synergy with Organic Carbon Stabilization ..... 2500

Thermal adaptation reshapes soil microbial carbon use efficiency under prolong warming ..... 2501

Influence of nitrogen fertilization and cover crops on soil microbial dormant fraction 2502

Response of Microbial Necromass and Extracellular Polymeric Substances under Multifaceted Global Change ..... 2503

Pathway-aware microbial phosphorus traits predict carbon-use efficiency and soil organic carbon turnover across urban gradients ..... 2504

From expansion to endurance: persistent warming reshapes soil active microbial communities in forest ecosystems ..... 2505

Microbes as engineers in modulating and preserving soil organic carbon ..... 2506

Effects of repeated freeze-thaw cycling on microbial activity in a temperate forest soil ..... 2507

Vertical distribution and controlling factors of soil microbial necromass carbon (MNC) under erosion–deposition processes ..... 2508

Microbial respiration, growth, and CUE - The roles of Land use, management, and environmental factors ..... 2509

Optimizing Soil Carbon Sequestration: Microbial Regulation by Straw Return Quantity and Frequency ..... 2510

Soil arbuscular mycorrhizal fungi mediate the contribution of microbial necromass carbon to soil organic carbon in rocky desertification areas ..... 2511

Nitrogen addition promotes soil microbial-derived carbon storage: A meta-analysis ... 2512

Microbial growth rate is a stronger predictor of soil organic carbon than carbon use efficiency ..... 2513

## Session 409011: Soil Organic Matter Transformation, Stabilization and Storage ..... 2514

Trade-off between Pore-Throat Structure and Mineral Composition In Modulating the Stability of Soil Organic Carbon ..... 2514

Roots enhance the accrual of mineral-associated organic carbon via new carbon formation and microbial conversion of native soil carbon ..... 2515

Organic acid-mediated destabilization overrides warming effect on soil carbon mineralization ..... 2516

Multi-element evidence that soil organic matter persistence is not attributed to selective preservation or loss but an ecosystem property ..... 2517

Root exudates drive grass-specific carbon sequestration through microbial networks in citrus orchards ..... 2518

Insights from soil-aggregate microbiome and in-field soil respiration for improved carbon sequestration assessment of land use practices ..... 2519

Short-term effects of Amynthas earthworms on litter decomposition and $CO_2$ emissions in a temperate forest ..... 2520

Straw input altered the composition of aggregate-associated organic carbon in soils with different initial carbon status ..... 2521

Ferrihydrite-mediated carbon stabilization and plant responses in an alkaline soil ..... 2522

Long-term organic amendment in a maize cropping system enhanced $CO_2$ emissions via stimulation of oligotrophic microbial decomposition of chemically recalcitrant dissolved organic matter compounds ..... 2523

A repeat-pulse field labeling study to trace the fate of $^{13}C$ and $^{15}N$ labelled canola and durum crop residues in plant and soil organic matter on the Canadian Prairies ..... 2524

Soil Carbon Dynamics and the Observer Effect ..... 2525

Rapid soil formation and carbon accumulation along a Little Ice Age soil chronosequence in southeast Alaska ..... 2526

Distribution Characteristics of Soil Labile Organic Carbon Fractions in Coastal Paddy Profiles with Different Fertility Levels ..... 2527

Toward a standardized and ecologically relevant framework for soil organic matter physical fractionation ..... 2528

Straw-Induced Carbon Dynamics in Saline Soils: Insights from $CO_2$ Emissions to Soil Organic Carbon Sequestration ..... 2529

Organic materials combined with microbial inoculants suppress priming effect and enhance SOC sequestration in sandy soil ..... 2530

Reframing Manure Amendments and Nitrogen Inputs as Co-Determinants of Persistent Soil Organic Carbon in Semi-Arid Agroecosystems ..... 2531

Molecular signatures of soil organic matter diverge under long-term manure versus straw amendments in agricultural Mollisols ..... 2532

Controls on the mineralization and stabilization of exogenous organic matter in volcanic soils ..... 2533

Amplifying the soil mineral pump for carbon sequestration ..... 2534

Straw incorporation stimulated the intercropping effect to enhance soil carbon sequestration ..... 2535

The Long-Term Impact of Excess Phosphorus Saturation on Soil Organic Carbon Sequestration in Agricultural Soils ..... 2536

Global warming and soil management impact on organic carbon stocks and dynamics in vineyard soils ..... 2537

Soil pH modulates the global soil organic carbon stabilization ..... 2538

Effects of Long-term Chemical Fertilizer Reduction Combined with Bio-organic Fertilizer on Soil Organic Carbon Fractions and Aggregate Stability in Tobacco-planting Soil ..... 2539

Effects of soil acidity on organic matter stabilization in Cryptomeria japonica and Chamaecyparis obtusa plantations ..... 2540

Mechanistic Shifts in Organic Carbon Stabilization in Black Soil under Acidification Stress Induced by Fertilization ..... 2541

Discovering the molecular basis for carbon storage in soil for food security and climate change mitigation ..... 2542

Controls on Temperature Sensitivity of Soil Organic Carbon Decomposition Along a Volcanic Elevation Gradient in California ..... 2543

Manganese oxides direct polyphenol carbon toward abiotic polymerization or oxidative decomposition: Effect of pH and molecular structure ..... 2544

$^{13}C$ tracing reveals organo-mineral regulation of carbon stabilization under ambient and elevated $CO_2$ levels ..... 2545

Mixing Rice straw with various N sources in a sandy soil: organic C stabilization and priming effect ..... 2546

Conversion of coastal marshes to croplands shifts the pool, composition and functional groups of soil organic matter ..... 2547

Influence on the structural stability of aggregates and soil organic carbon sequestration with different organic materials application: Analyzed from the perspective of the structure and properties of humic acid in aggregates ..... 2548

Soil organic matter formation from high P organic amendments ..... 2549

Dual and divergent formation pathways govern the composition and origins of mineral-associated organic carbon ..... 2550

Ancient radiocarbon-free organic carbon as a pervasive bias in soil $^{14}C$-based turnover estimates ..... 2551

Soil Carbon Stabilization and Site-Specific Drivers in Large-Diameter Timber Plantations of Southern China's Acidic Red Soils ..... 2552

Soil Carbon Stocks and Stable Isotope Profiles in South Korean Forested Wetlands across Successional Stages ..... 2553

Particulate pathway dominates mineral-associated organic matter formation and transformation ..... 2554

Effects of organic amendments on soil carbon stocks and their distribution between particle and mineral-associated organic carbons in a red pepper field ..... 2555

Iron-mediated mechanisms of soil organic carbon stabilization in paddy soils under warming and altered flooding ..... 2556

Distribution Patterns and Their Controlling Factors of Phytolith Abundance and Carbon Content in Mollisols (Phaeozems) of Northeast China ..... 2557

Iron oxides promote stable soil organic carbon sequestration in rice paddies ..... 2558

Assessment of carbon stock, stabilization, and soil aggregate structure in different Mediterranean agro-ecosystems ..... 2559

From waste to carbon sink: mineral-organic coupling in technosols ..... 2560

Tree species traits interact with site properties to shape soil organic matter composition ..... 2561

Fresh Plant Residues Drive Fungal Necromass Carbon Turnover to Stabilize Organic Carbon throughout the Soil Profile ..... 2562

A mechanistic investigation into the influence of mineral surface carbon loading on the formation of soil organic carbon ..... 2563

Effects of carbon-equal straw return on active organic carbon fractions in the black soil plow layer and maize growth ..... 2564

Soil Organic Carbon Fraction Dynamics Across Paddy Soil Profiles: A Critical Role of Parent Material ..... 2565

Effects of silicon modified biochar with different pyrolysis temperatures on carbon stabilization pathways in saline alkali soil ..... 2566

Microbial mediation of deep soil inorganic carbon accumulation under long-term straw return in alkaline agricultural soils ..... 2567

Sewage Sludge Biochar Is Less Persistent Than Plant-Based Biochars in Soil ..... 2568

Application of Clay and Iron Oxide-Amended Compost: Linking Emission Reductions to Enhanced Soil Aggregation, Necromass, and Plant Performance ..... 2569

The Interaction between Mineral Transformation and Mineral-Associated Organic Matter (MAOM) Degradation ..... 2570

Rapid versus delayed stabilization of residue-derived carbon by amorphous aluminum hydroxide and rice-husk biochar in alkaline soils ..... 2571

Soil Erosion and Organic Matter Stabilization Mechanisms ..... 2572

Iron-Mediated Carbon Dynamics in Coastal Wetlands under Seawater Intrusion ..... 2573

**Session 409012: The Challenge and Opportunity for Precise Assessment and Prediction of Soil Carbon Sequestration and Storage Across Spatial and Temporal Scales ..... 2574**

How no-tillage and cropping systems shape soil organic carbon formation and stabilization over time: Evidence from a 16-year chronosequence ..... 2574

Quantifying Soil Organic Carbon Deficits with Dynamic Baselines and Attainable Scenarios Modeled from Legacy Data ..... 2575

Equilibrium levels for SOC stocks under different environmental regimes ..... 2576

Microscale soil organic matter patches shaped by carbon- and nitrogen-rich microdomains ..... 2577

Enrichment of metastable iron minerals in global coastal wetlands ..... 2578

An approach to carbon credit finance feasibility assessment of SOC sequestration projects. ..... 2579

Straw return depth and tillage intensity drive changes in organic carbon fractions and their stability in black soil ..... 2580

Long-term field trials as a tool to evaluate the potential of fertilizers to maintain soil carbon persistence ..... 2581

Coupling of microbial carbon and energy fluxes in soil ..... 2582

Enhancing soil carbon sequestration and straw utilization through optimized microbial decomposition strategies ..... 2583

Latitude-dependent temperature thresholds reverse soil organic carbon losses in global Mollisol croplands ..... 2584

Field experiment reveals varied earthworm densities boost ..... 2585

soil organic carbon more than they increase carbon dioxide emissions ..... 2585

Impact of long-term tillage on the soil organic carbon storage and its composition in black soil ..... 2586

Soil Biogeochemical Models: Current Applications and Future Directions ..... 2587

Stover incorporation enhances soil carbon sequestration by improving the hydrophobicity of humic acid and soil water repellency ..... 2588

Crop diversity enhances soil total carbon via increasing inorganic carbon concentration ..... 2589

Estimating sequestration potentials of soil organic carbon in Black Soils of Northeast China ..... 2590

How Spatial Resolution Shapes Soil Carbon Estimates ..... 2591

Development of Non-destructive Soil Bulk Density Measurement Technology for Efficient and Precise Estimation of Soil Carbon Stocks ..... 2592

Parameters Optimization of RothC Model for Simulating Soil Organic Carbon Dynamics: A Case Study of Rice Straw and Soybean Residue Inputs ..... 2593

An Integrated Framework Combining Spatial Soil Carbon Information and a Calibrated RothC Model for Improving Cropland SOC Estimation ..... 2594

Manure addition enhances straw-derived soil organic carbon formation and accrual by regulating microbial metabolism in paddy soils ..... 2595

Using a historical a soil properties database (INFOSOLO) to analyse long-term variations in SOC, SOC fractions, and soil structure: a case study ..... 2596

Dynamics and Stabilization Mechanisms of Organic Carbon Fractions in Engineering Waste Soil During Intensive Amendment ..... 2597

The Carbon Sequestration Potential of Arable Soils in Russia Based on Dynamic Modeling ..... 2598

Soil Carbon Sequestration: Realism versus Potential ..... 2599

Dynamics of Soil Organic Carbon and Its Mineralization in Black Soils of Northeast China ..... 2600

Driving Factors and Spatiotemporal Variations of Soil Organic Carbon in the Northeast China Plain ..... 2601

Cultivation Management Reshapes Soil Profile Configuration and Organic Carbon Sequestration: Evidence from a 45-Year Field Study ..... 2602

Reconstructing rangeland soil carbon erosion using sediment trapped behind small reservoir dams ..... 2603

Conservation tillage and wheat straw managements improve soil organic carbon sequestration via calcium-mediated microbial communities and aggregate stability in Calcaric Cambisols ..... 2604

## Session 409014: Soil Organic Carbon: Accounting, Mechanisms, and Sustainable Management ..... 2605

Evaluating the Applicability of the RothC Model for Soil Organic Carbon Dynamics in Canadian Prairie Grasslands Using Physical Fractionation ..... 2605

Mid-Infrared Spectroscopy for Soil Organic Carbon Estimation: Global Insights and Case Studies ..... 2606

Enhancing spectral estimation accuracy of soil organic carbon by using geographic region and clay content as covariates ..... 2607

Integration of Smartphone Imagery with Topographic Parameters for Soil Organic Carbon Prediction in the Indo-Gangetic Plains: An Interpretable Machine Learning Approach 2608

Differences in the physical protection mechanisms of soil organic carbon with 13C-labeled straw and biochar ..... 2609

Recognizing and Reducing Effects of Moisture-Salt Coexistence on Soil Organic Matter Spectral Prediction:From Laboratory to Satellite ..... 2610

The influence of natural and anthropogenic pyrogenic history of the landscape on soil carbon stocks on example of Komi Republic ..... 2611

Underestimating Soil Carbon Dynamics: The Missing Role of Vertical Transport ..... 2612

A long-term global Mollisols SOC content prediction framework: integrating prior knowledge, geographical partitioning, and deep learning models with spatio-temporal validation ..... 2613

Field NIR Spectroscopy for Soil Carbon Monitoring in Hazelnut Orchards ..... 2614

Supporting environmental sustainability by increasing soil carbon sink through biowaste recycling and remote sensing integrated with machine learning ..... 2615

Engineered biochar amendments to address multiple soil constraints: Results from 12 field studies ..... 2616

Can we grow food on the Moon? Engineering biological systems in lunar regolith ..... 2617

Short term impact of biochar on soil total carbon, total nitrogen, $\delta^{13}C$ and $\delta^{15}N$ in two vineyards in Southeast Queensland of subtropical Australia ..... 2618

A simple gravimetric proxy for rapid, low-cost estimates across diverse subtropical soils ..... 2619

Biochar–microbial interactions as drivers of soil carbon sequestration: from heterotrophic priming to autotrophic $CO_2$ fixation ..... 2620

Biochar at scale needs long-term proof: LTE field trials supporting the green transition of Danish agriculture ..... 2621

## ABSTRACT

In this report, we compared the soils of two geographically and climatically different mountainous regions located in the permafrost zone: the Polar Urals (Yamal region of Russia, catena No. 1, C1) and the Qilian Mountains (Qinghai-Tibet Plateau, China, catena No. 2, C2). The two completely different regions of permafrost distribution were compared to understand the diversity of permafrost-affected soils and cryogenic ecosystems and further develop strategies for managing soil and biological resources in a changing climate. While peaks of the Qilian Mountains are over 5,000 meters high, the soil and vegetation belt here is usually distributed at the altitudes of 3,500-4,500 meters, giving way to rocks and mountain glaciers. In the Polar Urals, the soil and vegetation belt appears an average of 900 meters, where it is interspersed with open rock formations and glaciers, which are gradually disappearing. In addition to climate, the most important predictors of soil diversity in the studied regions are geogenic factors—soil-forming parent materials and relief. Despite several high peaks in the Qilian Mountains, there are vast areas with gentle slopes and eroded valleys, often covered with thick layers of diluvium, colluvium, loess and loess-like deposits, sporadically underlain by permafrost at depth more than 1 m. The mountain ridges of the Polar Urals are characterized by steeper slopes with less pronounced terraces. Slope deposits (colluvium, diluvium and talus deposits) are more developed, and the permafrost table is often located at a depth of 20-30 cm from the surface soil horizon. Thus, the depth of the active layer and the thickness of the fine-earth soil layer in the profiles are the main features that distinguish C1 from C2. The C1 sequence of the soils from the top of the ridge to the bottom of the slope includes following soil types: Leptosols, Cambisols, Cryosols (within one altitudinal belt) and Cryosols with specific caviar like structure (Cryomorphic soils). All the C1 soils are Hyperskeletic. The C2 soil sequence consists of Leptosols, Histic Cryosols, Cambisols, Mollic Cryosols, Podzols. Thus, under other equal conditions, the most developed solums are found in the soils of the C2, while soil development in depth in the C1 is limited by the high stoniness of the parent material and the shorter warm season.

## ABSTRACT

In recent decades, soil erosion has become a major environmental crisis, profoundly impacting ecosystems and natural resources (Sadeghi et al., 2025). This phenomenon has led to soil degradation and reduced fertility. Soil erosion is caused by the interaction of effective factors, including climate, soil erodibility, topography, soil management, conservation practices, and vegetation cover (Kiani-Harchegani et al., 2019; Dash & Maity, 2023; Badapalli et al., 2025). Among the factors affecting soil erosion, climatic and topographic factors are considered as important dynamic and static variables in soil erosion and sediment yield. Important topographic features include slope steepness and direction, and climatic features include rainfall, snow, and wind. These factors, directly or indirectly, affect other environmental factors, thereby altering soil hydrological processes. In calm, no-wind conditions, raindrops usually strike the ground vertically. Since wind is the driving force behind natural rainstorms, it can affect rainfall rates. Accordingly, wind-driven rainfall (WDR) can alter the characteristics of raindrops, including diameter, velocity, area, drop angle, and kinetic energy (Kalehhouei et al., 2023). The effect of this set of factors increases stress and activity in the surface soil aggregates, leading to the formation of cracks and rills on the soil surface. Accordingly, understanding the complex interactions between wind and rainfall is essential for monitoring and analyzing changes in water erosion. In this regard, the present study investigates the effect of WDR at different slopes and wind velocities. For the experiment, sandy-loam topsoil samples were collected to a depth of 20 cm from summer rangeland located in the Kojour watershed on the northern slopes of the Alborz Mountain in IRAN. After that, the prepared soil was transferred to three experimental plots measuring 6 m2 each. The soil surface of each plot was compacted with a hand roller to reach a bulk density of 1.46 g cm−3. For rainfall simulation, a rainfall intensity of 50 mm h-1 and a duration of 30 min were determined for a 30-year return period based on the intensity-duration-frequency (IDF) curves of Kojour Synoptic Station. Wind simulation was performed using two 1×1 m wind blowers, and the wind velocity produced by each was monitored with an anemometer. According to the wind rose of the synoptic station of the Kojour watershed, the prevailing wind velocity and direction in the region were approximately 2.9 m s-1 and northward. Wind velocities of 3 and 6 m s-1 were selected based on the experimental conditions and the possibility of wind generation. The wind direction in the experimental conditions was set to be upward. The characteristics of the cracks on the soil surface were measured after simulation using Digimizer software (Kalehhouei et al., 2025). Changes in raindrop characteristics at a 12% slope showed that, in no-wind conditions, the mean length, width, area, and perimeter of each soil surface crack were 6.04 cm, 4.72 cm, 20.18 cm2, and 18.67 cm, respectively. In contrast, the study properties under wind velocity of 3 m s-1 reached 7.32 cm, 4.96 cm, 25.47 cm2, and 20.12 cm, respectively. Similarly, under a wind velocity of 6 m s-1, the study characteristics increased to 10.14 cm, 7.65 cm, 33.21 cm2, and 26.83 cm. Also, results from changes in raindrop characteristics at a 30% slope showed that, in no-wind conditions, the mean length, width, area, and perimeter of each soil surface crack were 8.88 cm, 5.43 cm, 29.76 cm2, and 23.25 cm, respectively. In contrast, the study properties under wind velocity of 3 m s-1 reached 12.41 cm, 7.06 cm, 46.90 cm2, and 29.96 cm, respectively. Similarly, under a wind velocity of 6 m s-1, the study characteristics increased to 13.07 cm, 9.08 cm, 60.10 cm2, and 32.46 cm. In addition, at a 12% slope, in no-wind and wind velocities of 3 and 6 m s-1, 16, 25, and 32 cracks of different dimensions were formed on the soil surface, respectively. Also, at a 30% slope, under similar conditions (no wind and two wind velocities, viz., 3 and 6 m s-1), the number of cracks was 29, 36, and 40, respectively, and cracks of different dimensions were observed. These results indicate a significant effect of wind velocity and slope on the formation of cracks on the soil surface. The findings showed that, under WDR conditions, as the slope increased, the dimensional characteristics of cracks increased significantly ($P<0.01$). On the other hand, increasing wind velocity also significantly ($P<0.01$) increased the dimensional characteristics at the soil surface. The results of this study emphasize that increasing the slope significantly alters the dimensional characteristics of cracks. In no-wind conditions, cracks were distributed across the entire plot surface, but as wind velocity increased, they were mainly located in the middle and upper parts of the plot. The results of this study can provide managers and executives with comprehensive information for modeling soil erosion processes and for watershed conservation and management.

## ABSTRACT

The stabilization of soil organic carbon is facilitated by the interaction of organic matter (OM) with mineral surfaces. Given that both soil organic matter and mineral phases are heterogeneously distributed within the soil matrix at the microscale, the question arises whether the mineral phases preferentially co-locate with organic matter or whether their spatial distributions are independent. Combining the identification of distinct mineral phases with spatial mapping of organic matter within soil microstructures offers insights into soil organic carbon storage mechanisms. Here, we provide a novel two-step unsupervised segmentation of soil microaggregates in conjunction with mineral References to identify distinct mineral phases in intact soil microstructures and quantify the relative spatially distribution of OM to determine preferential co-location of OM and specific mineral phases.

By conducting nanoscale secondary ion mass spectrometry (NanoSIMS) measurements at 30 µm, we acquired elemental distribution of 19 References minerals covering common soil minerals under O- RF plasma, and resin-embedded intact soil microaggregates incubated with 15N-enriched litter (8.203 atom% 15N) under dual Cs+ and O- RF plasma. By applying this machine-learning approach in conjunction of mineral-dominated region of soil microaggregates and mineral References, we were able to distinguish mineral phases, such as calcite, iron oxides, illite and montmorillonite, in soil microaggregates. Nearest neighboring distance analysis revealed a preferentially spatial allocation between pre-existing OM and both calcite and iron oxides. Newly formed OM was found co-located with pre-existing OM or in the pore space, supported by the network analysis adjacent to native OM and non-active framework silicates. These findings demonstrate that the heterogeneous OM spatial distribution is not in random patterns but spatially co-located with specific mineral phases within biogeochemically diverse soil microstructures. These preferential allocation of OM to mineral phases reflect distinct OM stabilization mechanisms, like pore dependency and allow us to evaluate whether mineral reactivity serves as a reliable proxy, providing direct microscale evidence for mineral-specific pathways in soil organic carbon dynamics.

**ABSTRACT**

This study presents a comprehensive evaluation of soils and their agricultural potential in two locations in Southwest Nigeria, utilizing both morphological characterization and mapping-based classification. Soil samples were collected from various pedogenic horizons and analyzed for their physical and chemical properties. The soils were generally deep, ranging from sandy loam at the surface to sandy clay and clay in the lower horizons. The classification results revealed that the predominant soils in the study area are Alfisols, specifically classified as Ustalfs under the USDA Soil Taxonomy. The major soil types include Kanhaplustalfs, Paleustalfs, Kandiustalfs, and Haplustalfs, reflecting the presence of both argillic and kandic horizons. According to the World References Base classification, all pedons were identified as Lixisols, characterized by an argic B horizon with a cation exchange capacity (CEC) of less than 24 cmol (+)/kg clay and a base saturation of 50% or more. Notably, pedons varied into specific qualifiers such as Haplic and Ferric, particularly for those exhibiting Fe-Mn concretions. In Local Classification Series, soils were categorized within the Iwo Series and Ibadan Series, highlighting differences in texture and drainage properties. These findings revealed the diversity of soil types present, which is critical for informing effective agricultural management practices. Consequently, best management practices are recommended to enhance soil performance and sustain agricultural productivity across these regions.

*[1] Soil & Water Environment Division, National Institute of Agricultural Science, Rural Development Administration*

*Wanju 55365, Korea*

*dblee91@korea.kr

**ABSTRACT**

Drainage class is a critical factor in evaluating soil for crop suitability, water management, and sustainable agricultural planning. Traditional classification methods, which rely on field surveys and expert judgment, can be subjective. This study aims to establish objective criteria for soil drainage classification by analyzing color properties extracted from soil images. A total of 88 soil samples were collected from diverse parent materials and drainage classes. Soil colors were quantified using the Munsell soil color system, HSV, and CIELAB color spaces. In well drained and moderately well drained soils, matrix colors exhibited high chroma (≧3), while redoximorphic features showed low chroma (1–2), indicating strong oxidizing conditions. In contrast, poorly drained soils displayed grayish matrix colors with low chroma (≦2) and reddish mottles with high chroma (≧4), reflecting alternating redox conditions. Hue values in the HSV space and a* values in the CIELAB space were particularly effective in distinguishing drainage classes: well drained soils generally had higher Hue and a* values, whereas poorly drained soils tended toward lower Hue and negative a* values. Phyllite derived soils exhibited unique characteristics due to the inherent color of the parent material, highlighting the need for integrated interpretation. These findings demonstrate that digital image based soil color analysis, particularly using Hue and a* values, provides a quantitative and scalable approach to classifying soil drainage classes.

# Arbuscular mycorrhizal fungi hyphal density rather than diversity stimulates microbial necromass accumulation after long-term Robinia pseudoacacia plantations

## ABSTRACT

Robinia pseudoacacia plantations are an effective strategy for preventing soil erosion, enhancing soil fertility, and stimulating carbon (C) sequestration in barren systems, supported by symbioses with arbuscular mycorrhizal (AM) fungi and rhizobia. However, the effects of AM fungal diversity and hyphal density on microbial necromass and SOC accumulation after long-term Robinia pseudoacacia plantations remain unclear. We hypothesize that increased AM fungal diversity and hyphal density after afforestation stimulate SOC formation by facilitating fungal and bacterial necromass C (FNC and BNC), glomalin (GRSP), and extracellular polymeric substances (EPS), with the contributions increasing as forest age. To test this hypothesis, microbial necromass, SOC, AM fungal diversity, and hyphal density were measured in surface soil (0–20 cm) and subsurface soil (20–40 cm) of Robinia pseudoacacia plantations aged 10, 15, 20, 35, and >50 years. Results showed that SOC accumulation was largely confined to surface soil, predominantly as mineral-associated organic C (MAOC). The content of FNC, GRSP, and EPS-polysaccharide in surface soil also increased with stand age, which is closely associated with MAOC. This emphasizes that long-term Robinia pseudoacacia plantations primarily stimulate C accumulation in surface soil, likely due to GRSP and EPS-polysaccharide aiding in the aggregation and protection of microbial necromass C. Although the AM fungal diversity in surface soil decreased with stand age, the hyphal density increased alongside root biomass. The increase in hyphal density could facilitate FNC and EPS formation, thereby contributing to the MAOC and SOC accumulation. In contrast, the content of SOC and microbial necromass C in subsurface soil showed an absence of differences or was reduced. Overall, this study reveals that microbial necromass and SOC accumulation after Robinia pseudoacacia plantations occur in surface soil, with AM fungal hyphal density and associated exudates, rather than AM fungal diversity, serving as key predictors.

# Predicting the interaction of a coated moldboard plow and soil compared to the conventional one using adaptive neuro-fuzzy inference system (ANFIS)

**M. Askari[1*] and A. Nikbakht[2]**

[1] *Department of Biosystems Engineering, Faculty of Agricultural Engineering, Sari Agricultural Sciences and Natural Resources University, Sari, Iran*

[2] *Department of Engineering, School of mechanical, medical and process Engineering, Queensland University of Technology (QUT), Queensland, Australia*

*m.askari@sanru.ac.ir

## ABSTRACT

**Background and purpose:** The biggest disadvantages of the moldboard plow are excessive soil turnover and moisture loss, severe damage to the structure, increased soil erosion, and the sticking of wet soil to it. In this regard, coating the surface of the plow can help the soil move more smoothly and overcome the mentioned problems to some extent. The purpose of this study is to measure and predict the required draft force and the amount of soil fragmentation by the coated moldboard plow compared to the conventional one using adaptive neuro-fuzzy inference system (ANFIS).

**Materials and methods:** The independent variables included the plow type (conventional and coated), forward speed (3, 4 and 5 km/h) and depth (25, 30 and 35 cm). The dependent variables included the required draft force and the mean weight diameter (MWD) of the soil particles. 3 replications for each condition and a total of 54 plots were considered. The draft force was measured by a three-point frame-type dynamometer and the MWD of the soil particles was measured using shaker and sieves. Data were analyzed in SPSS and significant interactions were extracted using Genstat. Field data was used to train ANFIS in MATLAB (2021) software.

**Findings:** The results showed that the effect of plow type, forward speed and depth on the required draft force and the MWD of soil particles was significant ($P<0.01$). Regarding the interaction effects, only the two-way interaction of forward speed on plow type on the MWD of soil particles was significant ($P<0.05$). The highest and lowest values of the MWD were 35 and 14.1 mm at speeds of 3 and 5 km/h, depths of 35 and 25 cm in the coated and conventional plow, respectively. The highest and lowest values of draft force were 649.44 and 409 kg at speeds of 5 and 3 km/h, depths of 35 and 25 cm in the conventional and coated plow, respectively. Regression models predicted the draft force with higher accuracy ($R2=0.9275$) than the MWD ($R2=0.8236$). ANFIS best model (gaussmf) also predicted the draft force with higher accuracy ($R2=0.9998$) than the MWD ($R2=0.9988$).

**Conclusion:** It is concluded that the soil tilled by the coated plow was less disturbed and its MWD was larger, this type of plow also requires less darft force and is effective in saving energy consumption. if farmers are forced to use a moldboard plow, using this type of plow helps to stabilize and protect the soil structure while reducing energy consumption. The ANFIS approach, with its outputs, including three-dimensional graphs was more accurate than regression.

**ABSTRACT**

Extensive flat and stepped surfaces in the state of Tocantins (central-north Brazil) host broad areas of ferruginous duricrusts (Petric and Pisoplinthic Plinthosols) that play a key role in preserving and shaping the landscape. In the central part of the state, where siltstones and sandstones ofthe Pimenteiras Formation (Devonian, Parnaíba Basin) crop out, these soils are closely associated with the Lajeado Range and the Tocantins Depression. Summit Petric Plinthosols are characterized by intense lateritization and cementation, whereas the Pisoplintic Plinthosols profiles located in the depression show a lower degree of weathering, containing abundant alteromorphic nodules.

Ferruginous ooid micronodules were identified in thin sections associated with alteromorphic nodules in Pisoplinthic Plinthosols from siltstones ofthe Devonian Pimenteiras Formation in the depression. Initially, these nodules were interpreted as related to the parent material or as possible microfossils. However, detailed micromorphological observations revealed a pedogenic origin. In contrast, ferruginous ooid micronodules were not identified in the Petric Plinthosols ofthe summit. Therefore, thin sections from both ferrugínous duricrusts in the Tocantins Depression and in the Lajeado Range were examined under optical microscopy, and selected areas of interest were subsequently analyzed by SEM–EDS in order to identify the main pedogenetic processes responsible for ooid formation and to understand why they do not occur in the summit profile.

We identified that ooid formation begins with the epigenetic replacement of kaolinite booklets by hematite through the process offerrolysis. The lamellar morphology, unstable for iron oxides, undergoes centripetal reorganization, giving rise to hematitic ooids. Conversely, in the intensely lateritized summit profiles, kaolinite and hematite coexist, forming kaolinitic nodules cemented by ferruginous flows. Environmental variation—particularly topography and pH—likely plays a fundamental role in determining the weathering rate and, consequently, the pedogenic processes and morphological features produced.

## ABSTRACT

Soil pore structures at the microscale play a critical role in regulating water transport, gas diffusion, and biogeochemical carbon cycling processes. However, soil CT imaging inherently suffers from a trade-off between spatial resolution and scanning field of view, which often leads to insufficient resolution and structural discontinuity along the axial direction in three-dimensional CT volumes. These limitations significantly hinder accurate pore network reconstruction and multiscale soil process modeling. Conventional interpolation and super-resolution methods typically rely on local texture assumptions and struggle to preserve pore geometry and cross-slice continuity, frequently resulting in pseudo-pores and fragmented structures.

To address these challenges, this study proposes a segmentation-guided conditional diffusion framework with optical flow constraints for three-dimensional interpolative super-resolution of soil CT images. The proposed method integrates structural priors and spatiotemporal consistency constraints within a unified conditional diffusion paradigm to achieve physically consistent high-resolution reconstruction of soil pore structures. First, a soil-specific segmentation model is trained to extract robust pore probability maps from low-resolution CT slices, which are explicitly introduced as structural conditions into the diffusion denoising process. This guidance enables the model to focus on critical pore regions while suppressing non-physical texture generation. Second, to enhance inter-slice structural continuity, an optical flow–based constraint is incorporated to model correspondences between adjacent CT slices, effectively transforming the 3D interpolation problem into a temporally correlated conditional generation task. This design allows the diffusion model to capture pore morphology evolution and displacement along the axial direction. Furthermore, leveraging the strong distribution modeling capability of diffusion models, fine-scale pore structures are progressively restored through iterative denoising, mitigating structural distortion caused by one-step reconstruction strategies.

Extensive experiments were conducted on industrial soil CT datasets covering multiple soil types and scanning conditions. Quantitative results demonstrate that the proposed method consistently outperforms conventional interpolation techniques and existing 3D super-resolution models in terms of PSNR and SSIM. More importantly, evaluations based on pore-related physical indicators, including porosity, specific surface area, and pore connectivity, show high agreement between the reconstructed volumes and high-resolution References data. Qualitative visualizations further confirm that the proposed framework effectively recovers fine pore morphology while maintaining cross-slice structural coherence, significantly reducing pseudo-pore artifacts and axial discontinuities. In summary, the proposed segmentation- and flow-constrained conditional diffusion approach provides a robust and physically consistent solution for 3D interpolative super-resolution of soil CT images, offering reliable high-resolution structural data to support soil pore network modeling and carbon cycle research.

# Proto-soils of extreme environments: understanding chemical composition at a microscale with the use of Raman spectroscopy

**Nikita Mergelov**[1*]

[1] *Department of Soil Geography and Evolution, Institute of Geography RAS, Moscow, Russia*

*E-mail nikita.mergelov@gmail.com

**ABSTRACT**

A large portion of land is covered by proto-soils formed in the absence of vascular plants with root systems. Such soil bodies are common in various extreme environments, e.g., ice-free areas of Antarctica, High Arctic, arid and high-mountain regions. They normally have shallow profiles shaped by various microbial biofilms / cryptogamic biocrusts and represent the best available real-time models to approximate initial stages of soil formation in the Precambrian. Nowadays, they support such basic functions common to full-scale soils as carbon and nitrogen cycling, organic matter stabilization, transformation of minerals, and others. Given the specific microstructure of proto-soils with microbial horizons, their study requires sensitive non-destructive methods that have high spatial resolution, e.g., Raman spectroscopy. Here, we focus on the properties and microscale chemical heterogeneity of proto-soils with endolithic / hypolithic cyanobacteria-dominated microhorizons from East Antarctica and proto-soils under cryptogamic biocrusts from proglacial settings of High Arctic, all studied with the use of Raman microspectroscopy. The presentation is based on (1) single-spectrum Raman data obtained from point measurements of intact samples as well as on (2) hyperspectral Raman data analysis (chemometrics) and chemical maps obtained from thin sections with the spatial resolution of several microns. We revealed high spatial heterogeneity and redistribution of various components along proto-soil profiles. For proto-soils on non-carbonate rocks (gneisses, East Antarctica), a continuum of different calcium carbonate phases, including such polymorphs as calcite and aragonite, has been identified. It is likely that in situ weathering of Ca-containing silicate minerals contributed to the formation of CaCO3 here. In all proto-soils of East Antarctica and the High Arctic, Raman spectra contained bands of polyenes with heterogenous molecular structure, mainly various carotenoids. Raman bands of polyaromatic C, calcium oxalates (whewellite and weddellite), and Fe oxide-hydroxides (mainly hematite and goethite) were also common. Combinations of bands characteristic of Fe oxide-hydroxides and carotenoids, as well as of CaCO3 and carotenoids obtained from a volume of around 1 cubic micron, suggested spatially localized associations of these compounds. Overall, with the use of Raman microspectroscopy, we show that shallow profiles of proto-soils do not necessarily imply simplicity but instead may have very complex microscale patterns. Along with primitive profiles that have a single organogenic horizon of microbial and/or cryptogamic origin, they may also exhibit complex associations of paragenetic horizons and even profiles with eluvial-illuvial differentiation.

**ABSTRACT**

Drawing from discussions during the 17th International Conference on Soil Micromorphology, held in Puno, Peru, in 2024, the IUSS Executive Committee approved the establishment of the 'Digital Soil Thin Section Collections' Working Group, within Division 1 'Soils in Space and Time', in 2025. The goal of this Working Group is the establishment of an international framework for the digitization, characterization, archiving and sharing of soil thin sections collections. Several objectives have been identified, including: 1) Establish and maintain an international registry of soil thin section collections; 2) Develop soil thin section digitization technologies and techniques; 3) Establish international standards and guidelines for soil thin section digitization; 4) Digitize legacy characterizations and interpretations of soil thin section collections, as well as other associated data; 5) Establish open-access digital repositories (FAIR) of soil thin sections collections; 6) Develop AI-assisted techniques for advanced characterization of soil thin section collection imagery; and 7) Develop AI-assisted techniques for text mining of legacy documentation and data related to soil thin section collections. This presentation will provide an update on the development of the Working Group, as well as an opportunity to present and discuss plans for subsequent activities aimed at engaging the broader stakeholder community.

# Soil Profile Characteristics and Vertical Stratification Beneath Nabkhas in the Coastal Deserts of Oman

**Malak AL-Ghabshi[1*], Said Al Ismaili[1], Anvar Kacimov[1], Amna Al- Ruhaili [2]& Afrah Al Shukaili[1]**

**ABSTRACT**

Nabkhas are aeolian sand accumulations formed around desert vegetation and represent distinct pedological units within arid landscapes. This study examines the soil profile characteristics and vertical stratification of Nabkhas in Oman's coastal regions, with a focus on texture, moisture distribution, salinity, and dynamics of organic matter. Soil samples were collected from Nabkha bodies and adjacent interdunal areas and analyzed for moisture content, organic matter (OM), $pH_e$, electrical conductivity ($EC_e$), and selected soluble ions ($NO_3^-$, $Ca^{2+}$, $K^+$, and $Na^+$). Detailed vertical soil profiles were examined to assess textural layering and its influence on water retention and salt accumulation.

The results revealed pronounced vertical stratification beneath Nabkhas, characterized by coarse sandy surface layers overlying finer-textured loamy horizons at depths of approximately 60–150 cm. These fine-textured layers functioned as capillary barriers, significantly enhancing subsoil moisture retention (20.1–57.7%) compared to the overlying coarse sands (2.9–7.2%). Electrical conductivity increased with depth, indicating the accumulation of salt in lower horizons. Organic matter content was markedly higher beneath Nabkhas (up to 6.15%) than in surrounding interdunal soils (approximately 1.08%), reflecting enhanced pedogenic development. Despite these vertical contrasts, surface soil properties showed minimal differences between Nabkha and interdunal environments.

Overall, Nabkhas promotes the development of vertically differentiated soil profiles that enhance moisture storage and influence salinity distribution in arid coastal systems. These findings highlight the pedological significance of Nabkhas as localized zones of improved soil functionality within desert environments.

**ABSTRACT**

Micromorphological analysis of soil thin sections has traditionally been regarded as a qualitative or semiquantitative approach, while the global scientific community is advancing towards automated measurements and generation of large, high- quality datasets. Conventional micropedology studies primarily focus on features of the soil solid phase-–such as soil structure, solid mineral formations, mineral weathering, and coatings. However, many published soil descriptions remain incomplete, as researchers often emphasize only the features most relevant to their specific study objectives (Stoops et al., 2018). As a result, the full analytical potential of existing thin sections is frequently underutilized even though these samples remain preserved in institutional or personal collections and often represent soil profiles that are no longer accessible for field sampling. While there is great interest in conducting quantitative micromorphological studies, existing licensed software (e.g., ImagePro) is expensive and open-source tools (e.g., ImageJ) are very limited and/or require strong programming skills. Some previous work has applied Geographic Information System (GIS)-based solutions (Gutiérrez Castorena et al., 2018; Torres-Guerrero et al., 2023), but it also requires specialized skills in GIS analysis. To aid image analysis, some researchers apply pigments to soil samples as thin sections are being made, but these pigments may alter other soil properties in the thin sections. As such, all these existing methods are time-consuming and require either manual work or strong computational skills. The proliferation of Artificial Intelligence (AI) techniques may offer a solution, with computer vision leading to rapid advancements in image analysis across scientific disciplines. Greater computational resources, coupled with a growing number of open-source AI tools, are democratizing advanced image analysis, allowing users with little-to-no coding experience to use AI in their research. Here, we present one such example–a new open-source AI tool designed to quantify soil porosity in thin section imagery in a rapid and reproducible way–that will significantly reduce the time needed to perform, and eliminate existing barriers to, quantitative micropedology.

## ABSTRACT

Soil organic carbon (SOC) plays a fundamental role as one of the key and important components in soil health and ecosystem stability (Liang et al., 2025). SOC improves soil quality and reduces erosion by increasing water holding capacity and improving physical and chemical properties (Murphy, 2015; Page et al., 2020; Bai et al., 2025). SOC can also act as a carbon sink and prevent the release of carbon dioxide into the atmosphere and the increase in greenhouse gases (Lal, 2003; Mgalula et al., 2021). The presence of SOC can help create suitable habitats for microorganisms and other living organisms and increase biodiversity (Philippot et al., 2024). On the other hand, it can affect aspects of the economy and agriculture by increasing crop production and reducing the need for chemical fertilizers (Kamakaula, 2024). Some factors, including land-use changes (such as agriculture, deforestation, and urban development), climatic conditions (the role of temperature and precipitation on the decomposition of organic matter), and soil management (use of organic fertilizers) affect changes in SOC. The spatial distribution of SOC and the understanding of the factors affecting it are essential for better management of soil resources (Guo et al., 2025). Understanding the distribution of SOC has helped to provide a clear understanding of the biological and chemical processes of the soil, and to determine their effects on soil quality and ecosystem stability (Stanley et al., 2024). Among the factors affecting SOC are changes in land-use and slope direction. Land-use, such as the conversion of forests to cropland, can lead to a decrease in SOC, while appropriate management can help increase it. Also, slope direction has a great impact on the erosion and accumulation of SOC; the erosion rate is usually high on steep slopes. Therefore, by identifying and protecting sensitive areas and adopting appropriate strategies, soil quality can be maintained, ecosystem function and agricultural production can be improved. The present study aimed to investigate the effects of land-use and slope direction on SOC distribution in the Sari watershed, Mazandaran province, northern IRAN. This region, with its diverse vegetation cover and temperate and humid climatic conditions, is considered a suitable example for analyzing spatial patterns of SOC in foothill and plain areas. Three main data sources were used to conduct the present study. First, Sentinel-2A images with a spatial resolution of 10 m were used to produce a land-use map. The land-use categories included barren and sparse lands, urban areas, rainfed and irrigated agricultural lands, rangeland, and tree cover. Second, a SRTM digital elevation model (DEM) with a resolution of 30 m was used to extract the slope direction layer; the directions in this study were divided into four main groups: North, East, South, and West. Third, a global soil map (soil grids) with a resolution of 250 m from the ISRIC database was used to extract the percentage of SOC at surface depth. Data processing included aligning the layers to a single image system (corresponding UTM Zone) and creating an overlap between pixels to allow extraction of SOC values for each land-use category and slope direction. SOC was then categorized into five qualitative categories: very low, low, moderate, high, and very high based on the statistical distribution of values in the area. This categorization allows for a more detailed analysis of the relationship between land-use, slope direction, and SOC distribution. Analysis of the distribution of land-use areas in geographical directions showed that rainfed lands and tree cover have the largest share of area in the North (24.71% and 47.79%) and South (39.66% and 36.70%). While irrigated agricultural showed their largest share in the West (15.25%). Urban areas and barren and sparse lands had a smaller share in all directions, and the distribution of rangeland was also relatively uniform. These results indicate that the spatial distribution of land-uses is affected by slope and environmental factors and can play an important role in SOC accumulation in combination with geographical directions. Analysis of SOC in different land-uses showed that the highest share of soil with very low SOC was in barren and sparse lands (60.52%) and rangeland (57.76%). While tree cover and irrigated agricultural had the highest share in moderate to high categories. This pattern indicates the direct effect of vegetation cover and agricultural management on soil carbon accumulation. So that tree cover recorded the highest amounts of SOC with 28.17% in the high and 9.93% in the very high category, and irrigated agricultural also had high amounts of SOC with 32.26% in the moderate and 21.58% in the high category. Analysis of the effect of slope direction also showed different patterns. The South direction had the highest share of soil with low SOC (very low: 41.6% and low: 35.5%), while the North and East directions had higher values in the moderate and high categories. The West direction also showed a relatively balanced distribution of SOC in the moderate and high categories. These results emphasize that climatic factors such as solar radiation, temperature, and soil moisture in different directions play an important role in maintaining and increasing SOC. The combination of land-use analysis and slope direction showed that the spatial distribution of SOC was influenced by the interaction of these two factors. In particular, tree cover and irrigated agricultural were identified as areas of high SOC accumulation. While barren and rainfed in the South direction were the areas with the lowest SOC. These findings indicate that maintaining vegetation cover and applying appropriate management methods in agriculture can effectively increase soil SOC and be effective in reducing soil erosion and improving soil quality. Correlation analysis showed that there was a strong positive relationship between land-use type and SOC; tree cover had the highest positive correlation with high and very high SOC categories ($r \approx 0.68$) and irrigated farmland showed a moderate to high correlation ($r \approx 0.59$) with high SOC. In contrast, barren and rainfed lands had a significant negative correlation with high SOC ($r \approx -0.61$). On the other hand, slope direction also had a significant effect on SOC; North direction had a positive correlation with moderate and high SOC ($r \approx 0.57$), East direction had a moderate positive correlation ($r \approx 0.49$), and South direction had a significant negative correlation with low SOC ($r \approx -0.64$). The findings of the present study provide a comprehensive framework for spatial analysis of SOC based on land-use and slope direction and can be used as a basis for scientific decision-making for soil resource management and sustainable agricultural development in the study area. This region is located in Northern Iran and on the Caspian Sea coastline, and with its temperate and humid climate characteristics and diverse vegetation cover, it is considered an exemplary case for investigating the interactions between natural and human factors on soil health and carbon accumulation. The results of this study can help develop SOC management strategies, protect natural resources, and mitigate the negative effects of climate change in similar regions.

# Integrating Micro- and Submicromorphological Data for Diagnosing Redoximorphic Conditions in Soils of Topographic Depressions in the Oka-Don Lowland

**Kornilova A.**[1,2*], **Smirnova M.**[1,2]

[1] *Lomonosov Moscow State University, Moscow, 119999 Russia*

[2] *Dokuchaev Soil Science Institute, Moscow, 119017 Russia*

*kulikovanastya2001@yandex.ru

**ABSTRACT**

Defining soil water regimes-the interaction between saturation and redox conditions-remains challenging. Direct monitoring is constrained by resource-intensive long-term networks, necessitating robust indirect methodologies. Redoximorphic features provide valuable hydrological archives through their response to redox shifts. Comprehensive analysis of these features, supported by nodule elemental data and micromorphology, enables detailed characterization of water regimes and drainage patterns.

Our study employs an integrated macro-, micro- and submicro-morphological approach examining: i) the morphology, boundary sharpness, and elemental composition of redoximorphic features; ii) the thickness and material composition of illuvial clay features; and iii) the decomposition degree and spatial organization of organic matter.

We posit that macromorphological analysis provides initial diagnostics, micromorphology reveals pedogenesis, and SEM-EDS provides precise compositional data. This integrated approach develops criteria for hydrological reconstruction and tests micromorphological indicator reliability.

Applying this methodology to soils from nine depressions in the southern Oka-Don Lowland enabled us to delineate the hydrological regimes of three soil groups: Oxygleyic Gleysols (Clayic, Histic), Albic Mollic Gleyic Stagnosols (Clayic), and Albic Mollic Histic Planosols (Clayic).

Soils subject to prolonged groundwater saturation (Gleysols) are characterized by diffuse Fe-nodules, a general absence of clay coatings, abundant fresh and charred organic residues, and amorphous organic punctuations within the groundmass. In contrast, soils experiencing periodic, shorter-term waterlogging (Stagnosols and Planosols) exhibit sharply bounded, Mn-enriched redoximorphic features, well-developed clay and organo-clay illuvial coatings, a dominance of partially and fully decomposed organic matter, and a more integrated distribution of humus into groundmass. The nodule composition in Planosols contains more Mn than in Stagnosols, indicating more prolonged waterlogging in the latter.

The integrated analysis establishes that Gleysols develop under permanent saturation from both surface and groundwater sources, Stagnosols under periodic surface waterlogging with intermittent groundwater influence, and Planosols under solely surface saturation. This gradient reflects decreasing waterlogging duration Gleysols-Stagnosols-Planosols and shows how micromorphological signatures effectively characterize hydrological regimes.

# Final stage of loess accumulation in the periglacial zone of the Northern Caspian region.

**M.P. Lebedeva[1*], A.O. Makeev[2], E.B. Varlamov[1], R.E. Musaelyan[1], and N.A. Churilin[1]**

[1] *V.V. Dokuchaev Soil Science Institute, Moscow, Russia*

[2] *Lomonosov Moscow State University, Moscow, Russia*

* m_verba@mail.ru

**ABSTRACT**

In the Northern Caspian region, the final stage of Late Pleistocene loess accumulation was linked to transgressions and regressions of the Khvalynian Sea, which altered the composition and structure of parent materials. The maximum transgression boundary (48-50 m) extended to the foot of the Obshchy Syrt and the ridges of the Syrt Trans-Volga region. As the sea retreated, loesses accumulated on the exposed areas, and landscapes typical of the semi-desert zone in the southeastern Russian Plain began to form.

The most specific parent materials for soil formation in the Northern Caspian are the Lower Khvalynian chocolate clays (CC), whose maximum thicknesses are confined to the II terraces of the Volga and Ural rivers. Recent syntheses (Svitoch, 2015) on the properties, geography and occurrence patterns of these specific clays have shown that CC represent a complex litho-facial formation with layered texture and are not typical for the Volga-Ural interfluve area. Current dating of References sections in the Lower Volga region indicates that their accumulation occurred after the Last Glacial Maximum (17-13.1 kya). The highest accumulation rates of CC corresponded to the Bolling-Allerod period (14.7-13.2 kya, sea level 20-22 m). After 12.5 kya, the Yenotayevka regression developed (Kurbanov, 2020). On the interfluve surfaces (26-28 m a.s.l.) in the Dzhanybek endorheic plain, OSL dating was conducted on layers containing shells and CC fragments at depths of 60-90 cm in modern soils of dry-steppe solonetzic complexes. These studies (dating, micromorphology and minerology) revealed that the investigated CC and the upper loess layer, in which modern soils of the dry-steppe solonetzic complexes in the northern part of the Caspian Lowland have formed, entirely fall within the stratigraphic interval of the Lower Khvalynian deposits - they accumulated during the maximum Khvalynian transgression. The upper loess layer's distribution confirms final Late Glacial accumulation in the Northern Caspian periglacial zone. Our dates show loess formed during Ostashkov Glaciation decay under arid, cold conditions, causing fracturing, gypsum content, and cryogenic aggregation in CC layers and soil horizons. The thin loess layer shaped Holocene soils' lithology and with relict cryogenic features, explains the region's soil complexity.

# The Micromorphology of Brazilian Oxisols (Latossolos): variability and fertility connections of the most representative agricultural soil in the tropics

**Carlos Schaefer**[1*]

[1] *Department of Geography, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil*

*reyschaefer@yahoo.com.br

**ABSTRACT**

The Brazilian Oxisols (Latossolos, Ferralsols) are well-drained deep soils, weathered and, nutrient-poor, with a basic oxidic/kaolinitic mineralogy of low CEC and severe leaching. Despite the occurrence in all Brazilian territory, little is known about the variability of micromorphological characteristics of Oxisols across the country. We hypothesize that the Brazilian Oxisols present a considerable micropedologocal variability that is regionally manifested and traced according to the environmental characteristics of different Brazilian biomes. In this way, we compared the whole suite of Oxisols across the country (Latossolos Amarelos, Latossolos Vermelho-Amarelos and Latossolos Vermelhos) from Brazilian biomes, using robust legacy data produced by published soil surveys. The Red Oxisols (Latossolos Vermelhos) represent the suborder with the greatest degree of microstructural development and weathering, the highest contents of Fe and Al oxyhydroxides, clayey texture, greatest microaggregate roundness, pH and base saturation. Conversely, the Yellow Oxisols (Latossolos Amarelos) showed welded, coalesced microaggregates, combined with the highest contents of kaolinite, silt, sand. The Red-Yellow Oxisols (Latossolos Vermelho-Amarelos), in turn, presented intermediate characteristics, confirming that soil color is a key attribute for differentiating the microstructural development of Oxisols (Latossolos), regardless of the biome. The uniformity of chemical and mineralogical composition of the micromass at micraggregate scale reveals the long-term pedobioturbation for creating stable, minute aggregates of similar composition, despite the varying presence of silt-sized particles of Charcoal, quartz and Ti-bearing minerals. The importance of micropedology for fertility aspects, like P adsorption, is discussed.

# Stepped Canal and Levigation Pools in Teotihuacan, a study through their micromorphological and hydraulic relationships

**Ma. del Carmen Gutiérrez-Castorena[1*], Magdiel Irak Márquez Rivera[1], Sergio Gómez Chávez[2]**

[1] *Programa de Edafología, Colegio de Postgraduados, Texcoco, México.* *castor@colpos.mx

[2] *Zona Arqueológica de Teotihuacan. INAH. Mexico.*

**ABSTRACT**

Much of the city of Teotihuacan, including its everyday life and rituals, reflected the devotion and reverence of its inhabitants for water, as seen in murals, paintings, and ceramics. However, the discovery of a stepped canal, built during the Patlachique phase (200 BC–0 AD) and subsequently sealed during the Miccaotli phase (150–200 AD), provides an opportunity to document the Teotihuacans' earliest hydraulic works in detail. This research aims to analyse the micromorphological relationships among the different processes, sediments, and types of fills, as well as their relationships with hydraulic works. The 356-metre-long canal, which is 3.7 metres wide at the base and 1.4 metres deep, has four steps facing north and was discovered in 2002. It was explored through twelve test pits between 2003 and 2004. It is located north of the Citadel, running parallel to the San Juan River and perpendicular to the Calzada de los Muertos. Altered and unaltered samples were collected from each stratum or layer of the fill for laboratory analysis and thin sections. The results indicate that the stepped canal has all the necessary hydraulic characteristics to transport water. However, its location and design suggest that the water originated from the Calzada de los Muertos, rather than from the east as initially presumed. The presence of two spillways to the west of the structure and alluvial sediments whose thickness decreases towards the east provide evidence for the direction of runoff. Additionally, the presence of sediments comprising soil aggregates with an undifferentiated structure, followed by rounded tepetate particles (tuffs), indicates soil erosion and the exposure of the underlying material. This also demonstrates that the Calzada de los Muertos was not paved. The channel had traces of different fine sediments on its margins, indicating dredging down to the tepetate. A homogeneous layer of fine material, 10–25 cm thick, was identified on the tepetate, completely covering the channel base. This layer contains cavities and aggregates of various types, some of which have diatoms distributed randomly throughout. These features are characteristic of a process of selective extraction and filling, which probably served as a waterproofing agent. This filling was buried under a sequence of sediments with very fine laminations, composed of sands and silts with a banded distribution but no oriented clays, indicating that no clays were in suspension after the spill. These colloids were likely artificially separated and used to produce other items, such as ceramic artefacts, structural fillings, and adobe bricks. Accumulations of carbonised remains with calcareous ashes at the beginning of the canal suggest that rituals were performed there. In contrast, the parallel distribution of remains after the spillways indicates that rituals were not performed there. Finally, the hydraulic system was closed using materials from a new project that formed the San Juan River and crossed the city.

**Keywords:** fillings, sediments, spillway, erosion.

# Micromorphological Insights into Intra-Urban Spatial Dynamics: A Case Study from Oudenaarde (Belgium)

**ABSTRACT**

The diversity of anthropogenic soils in urban environments reflects shifts in land use and spatial organization, providing essential insights into human–environment interactions and stages of urbanization. A notable example is the widespread 'Dark Earth' (DE), a macroscopically homogeneous deposit that contains diverse micro-stratigraphic features, reflecting complex formation processes. This study employs soil micromorphology to examine how DE documents intra-urban soil variability and spatial dynamics within a historical context.

We analyzed DE from two sites in the historical center of Oudenaarde: one at the edge of town, next to a former canal (Broodstraat) and another at the central marketplace. A multi-proxy micromorphological approach was applied, incorporating analyses of soil organic matter, bone fragments, phytoliths, coprolites, and intestinal parasite eggs. Current results demonstrate that both natural and anthropogenic processes have contributed to the formation of both sites. The Broodstraat site reveals a predominance of natural processes, indicative of an urban wasteland near the Scheldt river. Ongoing analysis of the marketplace DE shows greater soil homogenization and intense reworking, suggesting frequent disturbances and managed urban use.

Overall, this comparative study highlights the value of soil micromorphology in decoding urban stratification and demonstrates how seemingly uniform anthropogenic soils in urban context can shed light on spatial dynamics and human–environment interactions in historical urban landscapes.

# Long-term nitrogen fertilization effects on soil mineralogy and micromorphology: The Magruder Plots

**Alexis Correira[1*], Brian Arnall[2], and DeAnn R. Presley[1*]**

**ABSTRACT**

Mineral weathering is heavily influenced by the soil forming factors including climate, topography, parent material, and biota, and humans have become a part of this process as well. The focus of this experiment is to explore the relationships between agriculture and soil weathering processes, specifically the relationship between soil minerals and long-term fertilization. Organic acids and other root exudate materials in soil environments play a role in the dissolution and transformation of soil minerals. Microbially facilitated denitrification reaction results in a net release of H+ and the application of nitrogen fertilizers can affect soil mineralogy as well, specifically increasing the amount of NH4+ fixed by 2:1 minerals and even in a relatively short timescale (Matocha et al., 2016; Bajwa, 1982). Evidence suggests that agricultural activity and inputs are changing soil properties that were previously understood to be inherent, like mineralogy and soil texture. Long-term experiments and soil archives provide unique opportunities to assess how soils change over time in response to land management. One long-term fertility experiment in the Great Plains region is the Magruder plots outside of Stillwater, OK, established in 1892. After over a century of cultivating continuous wheat, grain is still harvested from the zero-input check plot. These plots are iconic for the region as one of the oldest long-term experiments and the oldest continuous wheat trial in the country. However, there are no published mineralogical assessments on the plots to investigate potential changes driven by continuous tillage and nutrient amendments. There is a unique and interesting opportunity in these plots to further develop a whole-picture understanding of the relationship between soil minerals and agricultural management. Clay mineralogy and a suite of soil chemical measurements were completed, as well as macro- and micromorphological descriptions and the results will be discussed.

## ABSTRACT

Micromorphological examination of paleosols can be one of the most useful tools to reveal the pedogenic process that occurred in situ, from the original unweathered parent material to the current soil. In addition, paleosols record the local response to more global climatic and environmental changes especially over the Quaternary glacial and interglacial phases (Scarciglia et al., 2023). Pedogenesis, on a microscopical level, entails the weathering of primary minerals and rock fragments, resulting in the formation of secondary minerals and pedofeatures that provide key insights into the environmental conditions prevailing during their formation. In this light, soil micromorphology represents the well-known concept of "pedomemory" (sensu Targulian and Goryachkin, 2004), which is basically the soil capability of maintaining memory of the complex climatic and environmental settings of soil formation especially within micromorphological features. During the last decades micromorphology has been deeplyused to properly validate with a microscopic approach the existent classification of soils and to define differences among soil types (Wilding et al., 1985). Doing so, the most developed soils, like Ultisols usually found on the Pleistocene stable surfaces (Soil Tax, 1999), have been microscopically characterized mostly by the identification of illuviated clay and iron-bearing pedofeatures (Fedoroff & Eswaran, 1985; Cremaschi, 1987). Micromorphological description of paleosols is the key instrument to detect variability along a single profile and among different paleosols, which generally tend to exhibit similar macroscopic and chemical characteristics due to their high level of alteration (Birkeland, 1975). That approach even provides valuable insights into soil genesis and its evolution over time. Thus, the integration of macroscale characterization and chemical-mineralogical data - coming from the analysis on bulk samples - with the micromorphological observation is the starting point for a complete study of paleosols and it is regarded as an optimal strategy for the comparative study of paleosols (Fedoroff and Goldberg, 1982). Micromorphology is mainly a qualitative approach. With the aim of acquiring quantitative, statistically-sound micromorphological data, that may support comparisons within and among soil profiles, our study further tests the determination of the Representative Elementary Area (REA) (Vandenbyygart and Protz., 1999) for each microfeatures of interest (e.g. clay coatings, iron nodules, porosity, etc.), through image analysis of thin sections.

In the context of the research, micromorphology is applied to enhance the knowledge of paleosols in the southern-eastern Italian Pre-Alps, where Last Glacial Maximum deposits are well-detectable and older, strongly weathered glacial and glaciofluvial deposits are scattered along the current valleys of the Piave and Soligo rivers (Carton et al, 2009). In detail, two soil profiles (M25/01 and M25/02) approximately 9 meters in depth were excavated and sampled using Kubiena boxes or extracting blocks of oriented undisturbed soil. They both pertain to glaciofluvial terraces, likely pertaining to the Middle Pleistocene, located at a distance of ca. 17 km within the Venetian foothills (figure 1). M25/01 profile comes from the second order of fluvial terraces developed on the creeping anticline of the Montello Hill, shaped during the Quaternary by the combined action of the fluvial erosion by the antecedent Piave river and the simultaneous continuous tectonic uplift (Picotti et al, 2022). M25/02 profile pertains to the soil developed on the highest glaciofluvial terrace within the Soligo valley originated by the deposition of glaciofluvial sediments from the Piave glacier outwash system.

**Figure 1:** overview of the study area showing the position of soil profiles (red dots) and the stable geomorphic surfaces on which soil is developed (yellow polygons).

From a mesoscopic point of view, both soil profiles comprise a strongly weathered buried stony pedostratigraphic level overlain by loess deposit; they mainly differ in the mineralogical assemblages of the conglomeratic parent material, which is more carbonatic in M25/02 soil profile. Given the similarities of soil macroscopic features, micromorphological comparative study is needed to better characterize the two soil profiles and then reconstruct the past paleoclimate and paleoenvironmental conditions, taking to the formation of such developed soils. This approach allows us to cast light on the dynamics of the Pleistocene-Holocene landscape evolution and support the geomorphic-stratigraphic correlation of landforms and deposits across the study area.

# Medieval Urban Cultural Layers in Contrasting Arid and Humid Waterlogged Environments: Morphological and Chemical Properties, and Genesis

**ABSTRACT**

Cultural layers are soil-sedimentary deposits formed through complex interactions of simultaneous and successive anthropogenic and natural processes. Despite extensive research on archaeological urban deposits, the role of environmental conditions in shaping the characteristics and properties of cultural layers remains poorly understood.

This study presents a comparative analysis of more than 8 m-thick medieval urban cultural layers – Urbic Technosols (Archaic) – at two archaeological sites situated in markedly different environmental conditions: Veliky Novgorod (Dfb warm-summer humid continental climate according to the Köppen climate classification; flat topography; waterlogged conditions) and the Dzhankent fortified settlement in the Aral Sea region (BWk cold desert climate; paleodelta setting; groundwater influence at the bottom of the section). The research is based on an integrated approach combining macromorphological, micromorphological, and physicochemical analyses.

The results demonstrate that at both sites, the formation of cultural layers was dominated by intensive anthropogenic inputs and the accumulation of highly variable organic, mineral, and pyrogenic materials related to construction and domestic activities. However, the subsequent geochemical preservation of archaeological materials differs substantially and is primarily controlled by zonal hydrological and climatic conditions.

In the cultural layers of Veliky Novgorod, formed under persistently waterlogged, reducing conditions, processes and features of gleization, redox-driven migration of iron and manganese, clay illuviation, and phosphate segregation prevail. These conditions strongly suppress biological decomposition and promote exceptional preservation of organic matter, including anatomically preserved wooden and grassy plant remains, with total organic carbon contents reaching up to 39%.

In contrast, at the Dzhankent site, transformation processes are governed by an evaporative water regime, high alkalinity, and salinity. Dominant processes include humification and mineralization of organic matter, as well as intensive accumulation of easily soluble salts, gypsum, and carbonates. Despite suppressed biological activity, organic remains undergo pronounced abiotic degradation and are partially stabilized through mineral encrustation by carbonates and soluble salts, resulting in low organic carbon contents (0.4–3.1%).

The study demonstrates that even under comparable anthropogenic pressures, the direction and intensity of soil-forming processes and the degree of preservation of cultural layers are primarily determined by environmental conditions. Urban cultural layers thus function as long-term archives reflecting human–environment interactions under contrasting climatic regimes.

**ABSTRACT**

This study presents a pedological investigation of volcanic soils from central Apennine (Italy) and focus in a pasture area of notable ecological and cultural interest (1000 hectares), along historic transhumance routes (tratturi), now recognized as UNESCO Intangible Cultural Heritage. Four soil profiles were sampled along an altitudinal transect (1290-1360 m a.s.l.) made by the profiles: SM, CF, AS1 and AS2. SM is characterized by extremely dark brown topsoils with very high total organic carbon (TOC) content, reaching up to 77 g/kg. The topsoil overlies clay rich mineral horizons, likely developed from the Neapolitan Yellow Tuff (NYT) eruptive event. CF exhibits a thin topsoil resting on a "stone line" composed of siliceous gravel shaped by cryoclastic weathering. Below the discontinuity, the horizons show marked variations for structure and clay content. AS1 is characterised by shallow lithic contact and abundant glacial gravel derived from local denudation processes. In contrast, AS2 exhibits deep, lighter-coloured horizons enriched in manganese and iron concretions, together with a vertical sequence of buried BC horizons. Laminated pyroclastic layers (100-200 cm) in AS2 suggest episodic water stagnation and lacustrine sedimentation. Fepy/Feox (py/ox) ratios are low (0.1-0.2), and Alpy/Alox is 0.4-0.5 in surface horizons, increasing with depth, indicating vertical shifts in Al speciation (allophane/imogolite/Al-humus complexes); buried AS2 horizons reach Alpy/Alox > 1. Following WRB 2022, the profiles classify as (Aluandic) Andosols where andic properties are met (BD ≤ 0.9 kg dm−3, Alox+½Feox ≥ 2%, P retention ≥ 85%) and Siox < 0.6% in andic layers within 100 cm (≥15 cm cumulative). SEM-EDS shows elongated, highly vacuolar glassy fragments consistent with phytolith/opal-A (amorphous Si) from silicified grass tissues. The SEM images also reveal sub-spherical Mn-rich nodules with a distinctly concentric, laminated internal structure and massive outer rind, typical of pedogenic Mn-Fe nodules formed under fluctuating redox conditions. This layering indicates dissolution-reprecipitation cycles of Mn and Fe within the matrix, with Si and Al more diffusely distributed, implying that Mn-Fe oxides/hydroxides constitute the main sorbent phases against a silicate background. The combined effects of carbonate bedrock, distal volcanic inputs, karst geomorphology and mountain climate generate andic, organic-rich soils with intense Fe-Mn dynamics. These volcanic mountain soils underpin a wide array of essential ecosystem services, carbon sequestration, water and nutrient retention, pasture productivity, biodiversity and landscape stability. At the same time, they offer valuable References data for refining WRB soil classification and for guiding conservation-oriented management strategies within the Apennine pasture systems in central Italy.

# Micromorphological mechanisms reveal 45-year Anthropogenic barrier layer formation in Northeast China's Black Soil Region: pore connectivity collapse drives sustainable management imperative

**ABSTRACT**

The Northeast China Black Soil Region, a vital global grain production zone, is experiencing severe degradation of its fertile Brown soils (Luvisols) due to intensive agricultural use. This study investigates micro-morphological mechanisms behind degradation of Brown soil (Luvisols) in Northeast China by comparing undisturbed forest soil with adjacent soil under 45 years of dry farming. Combined thin-section and physico-chemical analyses show the profile evolved from Ah-AB-Bt-C to Ap1-Ap2-AB-Bt-C, forming a plow pan. Significant changes occurred: pH, organic matter, and total nitrogen decreased by 2.72%, 13.46%, and 9.79%, respectively, while bulk density, available phosphorus, and available potassium increased by 2.26%, 30.25%, and 14.97%. Micro-morphology revealed a lower coarse/fine particle ratio,higher circularity. The plow pan (Ap2) porosity decreased, while the argic horizon (Bt) porosity increased. Voids shifted from connected planar types to isolated vesicular vughs, and illuvial clay changed from large masses to thin coatings. The understanding for silica-neoformation pathways were also improved. These findings provide micro-morphological evidence of anthropogenic degradation and a framework for sustainable soil management in this critical agricultural region.

*carolinedelpupo@gmail.com

**ABSTRACT**

Cold volcanic landscapes of Iceland host young, ash-influenced soils where pedogenesis proceeds under low temperatures, episodic wetting and strong parent-material control, often while volcanic inputs and physical reworking continue. This study investigates micro-scale pedogenic features in such soils by integrating thin-section micromorphology with scanning electron microscopy coupled with energy-dispersive spectroscopy (SEM–EDS) and wavelength-dispersive spectroscopy (WDS). Thin sections from representative horizons were described using standard micromorphological criteria, with emphasis on groundmass organisation, microfabric, porosity and pedofeatures. Targeted SEM–EDS imaging and WDS spot analyses were used to characterise alteration rims on glassy particles and primary minerals, and to assess elemental redistribution linked to early weathering and short-range-order secondary products. Micromorphology reveals heterogeneous alteration of volcanic glass, ranging from fresh shards to particles with well-defined reaction fronts, alongside early microaggregate development. Pedofeatures include localised pore infillings and coatings around mineral surfaces, indicating microenvironments of enhanced moisture and solute availability. Microanalytical results show chemical differentiation at grain–matrix interfaces, consistent with incipient formation of secondary Al– Fe–Si phases and iron-rich coatings, as well as local concentration gradients suggestive of limited translocation at very short distances. The close juxtaposition of unaltered and altered materials within single thin sections suggests that early pedogenesis is spatially discontinuous, controlled by microscale variations in parent material texture, porosity and short-range hydrological pathways. By combining micromorphology with SEM-based microanalysis, this study provides process-based evidence for the initial stages of soil formation in cold volcanic environments and clarifies how pedogenic signals emerge within volcanogenic parent materials. The findings contribute to conceptual models of soil genesis in Icelandic landscapes and offer micro-scale constraints relevant to the classification and interpretation of young volcanic soils across cold-region settings.

*20171026@gdufe.edu.cn

**ABSTRACT**

The dryland farming practices embodied in the Yangshao culture (5000–7000 B.P.) represent a precious agro-cultural heritage that profoundly influenced the development of Chinese civilization. Current research on primitive agricultural systems in northern China remains relatively limited. Enhancing the documentation and study of relevant farming techniques and heritage sites is therefore essential. Such work can provide a foundational basis for nominating significant sites as National or Globally Important Agricultural Heritage Systems.

This study employs an integrated methodology, including field survey of soil profiles, basic physico-chemical analysis, and soil micromorphology, to extract evidence of ancient cultivation from multiple cultural layers at the Yangshao Village site. The aim is to characterize agricultural practices during this critical period.

Results indicate that the cultural layers are predominantly gray-brown in color and contain inclusions such as pottery shards, bone fragments, and charcoal. These layers exhibit elevated total nitrogen content and significantly higher concentrations of total phosphorus and calcium carbonate compared to adjacent, non-anthropogenic soils. The soil matrix and aggregates within the cultural layers show marked heterogeneity, indicating the incorporation of diverse anthropogenic materials.

Micromorphological observations reveal specific features linked to human activity: iron oxides and black charcoal derived from fire use; crystals and aggregates associated with altered soil conditions; and fecal pellets likely resulting from organic matter addition (e.g., manuring). These features, along with micro-laminations and disrupted soil fabrics, provide direct evidence of soil cultivation, fertilization, and irrigation practices.

A strong correlation was found between the macroscopic observations, physico-chemical data, and micromorphological features. This multi-proxy correlation enabled the classification of activity areas at the site into zones of high and low probability for ancient cultivation. Paleotopographic reconstruction further suggests that early human activity, particularly cultivation, began in lower-lying areas. These practices appear to have contributed to the development of a stable, sponge-like soil microstructure.

In conclusion, the macroscopic and physico-chemical properties of the soils are fully consistent with the micromorphological evidence, confirming that these are anthropic soils (Anthrosols) formed through ancient human fire use and intensive farming. This research demonstrates the effectiveness of a multi-disciplinary approach in identifying and interpreting ancient agricultural practices, providing concrete evidence for the sophisticated land management of the Yangshao culture.

# Species-Specific Impact of Earthworm Ecological Groups on Soil Coprolite Physico-Chemical Properties and Microstructure

**Agnieszka Józefowska[1*], Karolina Feluch[2], Łukasz Uzarowicz[2] and Mateusz Suchanek[1]**

[1] *Department of Soil Science and Agrophysics, University of Agriculture in Krakow, Krakow, Poland*

[2] *Department of Soil Science, Institute of Agriculture, Warsaw University of Life Sciences – SGGW, Warsaw, Poland*

*agnieszka.jozefowska@urk.edu.pl

**ABSTRACT**

Earthworms function as critical soil ecosystem engineers, fundamentally altering soil physical architecture, porosity, and the effective circulation of nutrients, notably nitrogen (N) and phosphorus (P). Their activities enhance soil structure and fertility. This study investigated the distinct, species-specific impacts of three major ecological earthworm groups—Aporrectodea caliginosa (endogeic), Lumbricus terrestris (anecic), and Dendrobaena veneta (epigeic)—on the physico-chemical properties and microstructure of soil coprolites produced over a nine-week mesocosm period. The initial soil substrate had an alkaline pH of 7.83. Analysis included quantifying pH, Organic Carbon (OC), Total Nitrogen (TN), and the Carbon to Nitrogen (C:N) ratio. Advanced image segmentation of micromorphological thin sections was used to quantify the relative contribution of mineral matter, organic matter, and pore space fractions.

Coprolites generally exhibited a higher pH than the surrounding soil, confirming a known effect of earthworm activity. The endogeic species, A. caliginosa, produced coprolites with the highest OC (2.36%) and TN (0.22%) content. Furthermore, A. caliginosa created the most water-resistant aggregates, with a Water Resistance Index (WRI) of 0.59, confirming its role in strengthening soil structure. Conversely, the epigeic species, D. veneta, which relies primarily on surface organic matter, generated coprolites characterized by the lowest C:N ratio (7.75).

Micromorphological analysis revealed significant compositional differences linked to feeding strategy. D. veneta coprolites contained minimal mineral content (2.9%) and high organic fractions (65.9%). This contrasts sharply with the endogeic and anecic species (A. caliginosa and L. terrestris), which demonstrated strong mixing of the mineral soil component with organic matter. These results emphasize that the ecological grouping and associated feeding habits of earthworms drive distinct coprolite compositions, significantly influencing soil aggregation potential and nutrient availability.

# Microscopic morphological characteristics of the Albic horizon in the Black Soil Region of Northeast China

**Xin-Yu Liu[1*], Zhong-Xiu Sun [1], Si-Yi Duan [1], and Ying-Ying Jiang [2]**

[1] *College of land and environment, Shenyang Agricultural University Shenyang, Liaoning CHINA*

[2] *Shenyang Institute of Technology Shenyang, Liaoning CHINA*

*xinyuliu020112@163.com

**ABSTRACT**

Albic soil, a typical low-yielding problematic soil in Northeast China's black soil region, faces the albic horizon as the primary impediment to agricultural productivity. This horizon is characterized by compact texture, limited nutrient and water mobility, nutrient deficiency, and uneven spatial distribution, which collectively restrict root penetration and severely constrain regional grain production and sustainable agricultural development. Through field surveys and microscopic analyses of thin sections from collected albic soil samples, this study systematically examines the morphological features of mineral composition, pore structure, and biotopes, alongside their interrelationships, to uncover the micro-mechanisms underlying albic horizon formation. The findings reveal that the albic horizon exhibits high silty sand and low clay content, with iron- and manganese-deficient pale leaching layers displaying 2–3 mm flake-like structures and an average thickness of 18–22 cm. Its pore structure demonstrates vertical reduction and horizontal expansion: under waterlogged conditions, ferric iron in the subsoil reduces to ferrous iron, with some migrating laterally via soil solution and others leaching downward through organic matter complexation; in arid conditions, ferrous ions oxidize back to ferric states, forming localized nodules that co-precipitate with clay. Furthermore, under acidic conditions—particularly from organic matter decomposition—aluminosilicates precipitate. During micro-scale precipitation, particles smaller than 0.25 mm form micro-aggregates or monoliths that coalesce into dense structures through cementation, potentially serving as the key micro-mechanism driving soil compaction. These insights collectively advance the understanding of albic horizon genesis and provide a scientific basis for mitigating its constraints on agricultural productivity in the region.

**ABSTRACT**

Loess-paleosol in the Chinese Loess Plateau is a valuable archive of climate change and soil pedogenesis. Nevertheless, knowledge of the interactions between soil magnetism and underlying geochemistry (i.e. geochemically relevant elements) are limited, especially on the eastern of Chinese Loess Plateau. To address this gap, we collected a new soil/paleosol sequence (21 m depth) and applied a range of rock magnetism methods, diffuse reflectance spectroscopy, and x-ray fluorescence measurements to establish a relationship between magnetic properties and geochemical element ratios from Fushan in the eastern of Chinese Loess Plateau. The results suggested that Fushan loess/paleosol sequence was deposited between 0.75 to 0.15 Ma, and is characterized by fine-grained magnetite/maghemite and goethite, with the single-domian (SD), pseudo-single domain (PSD) and multiple domain (MD) grain sizes. The correlation between magnetic susceptibility and Rb/Sr, Ca/Ti ratio in particular reflected the intense pedogenesis controlled by the East Asian summer monsoon. Magnetic susceptibility and diffuse reflectance spectroscopy revealed three significant climate change events corresponding to 1) specific stages of the global ice age (0.75 to 0.54 Ma), 2) a transitional period between the ice age and the interglacial period (0.54 to 0.28 Ma) and 3) the gradual approach of a new ice age (0.28 to 0.15 Ma). The relationship between soil magnetism and geochemical elements can therefore provide a new perspective for understanding past changes to climate.

## ABSTRACT

Soil heavy metal pollution has becoming one of the most serious global environmental problems due to its potential impact on human health especially for urban industrial areas. As a method with advantages of rapidness, sensitiveness, cost-effectiveness, and non-destructiveness, environmental magnetism has been widely applied in many fields including soil heavy metal pollution monitoring. Many previous studies showed obvious soil magnetic enhancement along with increasing heavy metal contents and proved some magnetic parameters can be used for heavy metal pollution monitoring. However, the wide application of magnetic method in heavy metal monitoring is limited due to the complexity and spatial heterogeneity of the occurrence relationship between heavy metals and magnetic particles as well as the influences of natural pedogenic particles.

In order to unravel soil magnetic properties and their correlation and implication between/for heavy metal pollution for industrial areas within megacities, one hundred and two surface soil samples collected from the Huangpu industrial area within Guangzhou city were selected for detail environmental magnetic measurements. Based on statistical analyses of environmental magnetic results, thirteen and fifty-six representative samples were selected for rock magnetic and heavy metal content measurements, respectively. In order to unravel the relationship between heavy metals and magnetic minerals within topsoils, correlation and factor analyses are performed using environmental parameters (logarithmically transformed to conform to normal distribution) and *Igeo* of every heavy metal element as well as $I_{MN}$. Furthermore, multiple linear regression analysis (stepwise) was conducted using content of each heavy metal element (logarithmically transformed to conform to normal distribution) as the dependent variable and magnetic parameters as the independent variables.

The environmental magnetic results indicate that the main magnetic carriers within the measured soil samples are minerals of iron oxides within coercivity range from 20 mT to 300 mT. The values of concentration magnetic parameters are obviously higher and relatively high spatial variability than natural and agricultural soils within the study area (Bian et al, 2014; Chen et al, 2025). Within all measured samples, only one soil sample has similar $_{fd}$(%) value (6.1%) to natural formation soils, the $_{fd}$(%) values of other one hundred and one soil samples are less than 1%, suggesting that the contribution of SP to magnetic susceptibility can be neglected. Moreover, the $_{ARM}$/SIRM values of all measured soil samples are ranged from 2.65 to 62.21*$10^{-5}$ m/A, indicating that magnetic particles within soil samples are MD+PSD and Coarse SSD (Dearing et al, 1997). In addition, the King plot of all measured samples indicate that particle size of magnetic minerals are coarser than 0.2 m and even than 5.0 m. Rock magnetic results such as hysteresis loops, IRM acquisition and reverse demagnetization curves indicate that the remanent coercivity of all measured soil samples are less than 60 mT. Furthermore, magnetic susceptibility variation during heating processes illustrated by -T curves suggests the main magnetic minerals should be magnetite phase and some small amount of high coervicity minerals such as iron hydroxides or hematite. Consequently, three magnetic components with respective average $B_{1/2}$ of 4.7 mT, 43.3 mT, and 632.1 mT and respective average IRM contribution of 3.1%, 85.5%, and 11.4%, indicating the predominated coarse magnetite mineral phase.

According to soil heavy metal pollution assessment results published by Zhou et al (2022), most of the measured soil samples are moderately to seriously contaminated by heavy metals Cu, Zn, Pb, Cd. As shown in Figure 1, significant differences of magnetic properties are appeared among different pollution level soil samples.

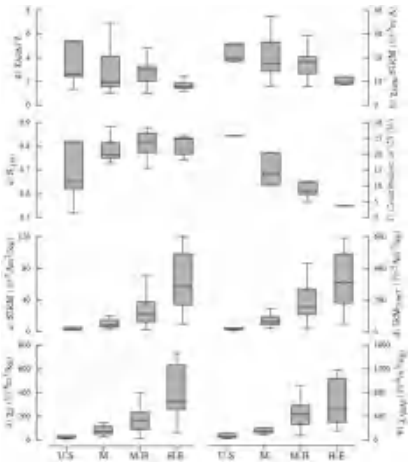

Figure 1 Comparison of magnetic properties among different pollution level samples (U-S, M, M-H, and H-E represent uncontaminated to slightly contaminated, moderately contaminated, moderately to heavily contaminated, and heavily to extremely contaminated, respectively). a) lf (10-8 m3/kg), b) ARM (10-8 m3/kg), c) SIRM (10-3 Am2/kg), d) IRM20mT (10-5 Am2/kg), e) S-100, f) IRM contribution of C3 (%), g) ARM/ , h) ARM/ SIRM (10-5 m/A)

Soil magnetism is significantly enhanced by anthrogenic input heavy metals due to continuous increasing values of concentration dependent magnetic parameters (Figure 1a, b, c, d) along with more seriously pollution. The values of $S_{-100}$ (Figure 1e) and IRM contribution of C3 (Figure 1f) are respectively increased and decreased from uncontaminated to extremely contaminated samples, indicating a decreasing content of natural pedogenic hematite with increasing heavy metal pollution. The variation trends of ratio parameters (Figure 1g, 1h) further proved that magnetic particles are become coarser along with the increasing heavy metal pollution.

Except for Hg, *Igeo* of other heavy metals and $I_{MN}$ are significant positively correlated with concentration dependent magnetic parameters $_{lf}$, $_{ARM}$, $_{fd}$, SIRM, HIRM, $IRM_{20mT}$ as well as S-ratio. On the contrary, significant negative correlations are appeared between HARD, $_{ARM}$/SIRM and *Igeo*, $I_{MN}$. The mentioned results manifest that heavy metals are coexisted with coarser low coercivity magnetic particles. *Igeo*_Hg is positively correlated with $_{ARM}$, $_{fd}$, SOFT, $_{ARM}$/SIRM, and $_{ARM}$/ , indicating that Hg should be coexisted with low coercivity fine magnetic particles such as SP and SD magnetite.

Factor analysis yields four principal components with Eigenvalue larger than 1, explaining 84.9% of the cumulative variance. The C is significantly positive correlated with magnetic parameters $_{lf}$, $_{ARM}$, $_{fd}$, SIRM, HIRM, $IRM_{20mT}$, $S_{-300}$ and $I_{geo}$ of heavy metals Cu, Zn, Ni, Pb, Cr, Cd, As, and comprehensive pollution index $I_{MN}$, indicating that C1 can represent the anthrogenic input of the mentioned heavy metals and most of magnetic particles. As for the second principal component, ratio magnetic parameters SIRM/ , $_{ARM}$/ $_{ARM}$/SIRM and $I_{geo}$_Hg have significant positive loadings, suggesting C2 may represent input of finer magnetic particles. Simultaneously, $I_{geo}$_Hg is also significantly positive with C4 which has obvious high loading for $S_{-300}$. These results indicate that Hg may be coexisted with fine low coercivity magnetic particles. Except for a positive correlation with C1, HIRM is concurrently negative related with C3. Meanwhile, C3 is also positively related with $S_{-300}$. Therefore, it can be deduced that C3 should represent generation of hematite through natural soil formation. Interestingly, no obvious correlation is appeared between C3 and all measured heavy metals, proving that these heavy metals are derived from anthrogenic sources.

According to the less than 0.001significance reflected by the $R^2$ values and scatterplots between predicted and measured cumulative probability (P-P plots), it can be concluded that the regression models are reliably and can be used to analyze the occurrence of heavy metals and magnetic particles and to predict soil heavy metal contents. Contents of Cu, Zn, and Cr can be predicted and inverted using SIRM which reflects the content of magnetic particles (especially coarser particles), indicating that these elements may be tended to coexist with coarser magnetic particles in soils. Heavy meatal Ni can be predicted and inverted by $_{ARM}$ and SOFT (respectively positive and negative correlation), indicating that Ni in soil tends to coexist with SD magnetic particles with a coercivity greater than 20mT. Heavy metal As can be predicted and inverted using $_{ARM}$, indicating that As in soil tends to coexist with SD magnetic particles. Pb in soil tends to coexist with magnetic particles coarser than SP particles. Cd can be positively predicted and inverted using SIRM and $S_{-300}$, indicating that Cd in soil tends to coexist with coarser soft magnetic particles. In the regression model for Hg, magnetic parameters $_{ARM}$/ and $S_{-300}$ are selected and positively correlated, indicating that Hg in soil tends to coexist with finer soft magnetic particles. Overall, soil heavy metal pollution is mainly affected by anthrogenic input of coarse magnetic particles with coercivity greater than 20mT. Therefore, magnetic parameters SIRM, $IRM_{20mT}$, and $S_{-300}$ are suggested for soil heavy metal pollution monitoring within industrial areas.

The present findings and the established regression models can give some References for deep understanding of magnetic response to soil heavy metal pollution and the application of magnetic method in soil heavy metal monitoring.

# Study on Optically Stimulated Luminescence Dating and developmental model of alpine meadow soil in ThreeRiver Headwater Region

**ABSTRACT**

The formation age and pedogenic development of alpine meadow soils in the Sanjiangyuan (Three Rivers Headwater) region are crucial for understanding soil-forming processes on the Qinghai–Tibet Plateau. In this study, twenty-one alpine meadow soil profiles were investigated across the Sanjiangyuan area. Optically stimulated luminescence (OSL) dating was applied to both the grass-mat (turf) layer and the parent-material layer, and particle-size characteristics were analyzed to reconstruct soil developmental processes. In addition, soil magnetic properties were considered as complementary indicators of pedogenic intensity and dust input.The results show that the grass-mat layer of alpine meadow soils generally formed within the last 1 ka, whereas most parent-material layers developed since the last deglaciation, with a few dating to interstadial phases of the Last Glacial period. Grain-size distributions of parent materials commonly display a distinct trimodal pattern, with a dominant peak at 40–60 μm. The grain-size frequency curves closely resemble those of typical loess deposits, indicating that aeolian dust represents a major source of soil parent material in the region. Consistent with the grain-size evidence, enhanced pedogenic magnetic signals in surface and near-surface layers suggest intensified pedogenic modification and effective trapping of fine aeolian particles during soil development.From the last deglaciation to the Holocene, climatic fluctuations exerted strong control on dust-input rates and pedogenic intensity. Parent-material ages cluster mainly in the late Holocene, implying strengthened aeolian activity under cold–dry climatic conditions, which provided essential materials for alpine meadow soil formation. Overall, the combined evidence from OSL chronology, particle-size characteristics, and soil magnetic properties demonstrates that alpine meadow soils in the Sanjiangyuan region developed under a “mixed parent material–aeolian accretion” pedogenic model, highlighting their high sensitivity to climatic and environmental changes.

# Impacts of Vehicular Non-Exhaust Emissions on Magnetic Enhancement and Heavy Metal Accumulation in Urban Road Dust

**Xin-Ming Ying*, Le-San Mei, Xue-Feng Hu**

*School of Environmental and Chemical Engineering, Shanghai University, Shanghai 200444, China*

E-mail Address: yxm4869@shu.edu.cn

**ABSTRACT**

In recent years, with the popularization of electric vehicles and improvement of fuel quality, vehicular exhaust emissions have significantly decreased, while the proportion of non-exhaust emissions has increased. Non-exhaust emission particles are characterized by their fine size and complex composition, of which, the friction particles from vehicular brakes contain 43%-75% of metallic Fe and Fe oxides, and 1-2% of other metals. Fe-rich particles tend to adsorb heavy metals such as Ni, Cu, Zn, Ba, Cd, Pb, and Mn within their structure tightly. Therefore, magnetic parameters can be used to evaluate the content of Fe and heavy metals in soil and sediments.

Fe-containing fine particles from industrial activities and vehicular non-exhaust emissions have become a major source of suspended magnetic particles in urban atmosphere. To study the impact of deposition of atmospheric magnetic dust on the urban environment and soils, a total of 203 dust samples were collected on solidified road surface in the areas strongly influenced by traffic, commercial or industrial activities in Shanghai, Southeast China. Each dust sample was divided into coarse (0.149-2 mm) and fine (<0.149 mm) fractions. Their magnetic, geochemical, and mineralogical properties of the dust were analyzed, compared with these of powder of brake pads. Magnetic susceptibility (χlf) of the coarse and fine fractions of the road dust was 555.69 × 10-8 m3 kg-1 and 667.88 × 10-8 m3 kg-1 on average, respectively, which was 19-23 times the magnetic background value of the soils in Shanghai. The χlf of the road dust in the different areas followed the decreasing order of the industrial area > the traffic > the residential. Frequency-dependent susceptibility (χfd%) of the road dust was mostly less than 2%, indicating that the magnetic particles in the road dust were dominated by anthropogenic coarse multi-domain (MD) and stable single-domain (SSD) particles. The χlf value of the road dust was significantly negatively correlated with the content of Cd, Co, Cr, Fe, Mn, Ni, Zn, and the pollution load index (PLI) ($p<0.01$), suggesting its effectiveness as a pollution indicator. The source analysis indicated that the industrial activities dominantly contributed Fe, Mn, Ni and Cr in the road dust, while the brake wear is an important source of Ba, Cu, Sb, Pb and Zn. The Cu/Sb ratio in the coarse fraction of the road dust in the traffic, industrial and residential areas was 11.40, 20.75 and 22.66 on average, respectively. That in the traffic area was close to the characteristic value of brake wear particles (4.6 ± 2.3). The fine fraction of the road dust in the different functional areas showed the similar patterns of Cu/Sb ratio. This highly suggests the significant influences of vehicle non-exhaust friction wear particle emissions, especially brake wear particle release, on road dust accumulation. Continued atmospheric magnetic dust deposition profoundly affects urban surfaces and soil formation.

# Vertical distribution of magnetic property of urban soil profiles in Shanghai and its environmental implications

## ABSTRACT

Eighteen soil profiles were set up in the five areas, including an agricultural field at Luojing Town, a residential area at Dachang Town, a greening belt beside traffic lines, and industrial sites at the Shidongkou and Wusong Parks in Baoshan District in the northern part of Shanghai, Southeast China, to study the magnetic characteristics and heavy metal contents in the urban soils.

The agricultural soil has a weaker magnetic signature, close to the local magnetic background. In contrast, the magnetic signatures of the soils in residential, traffic lines, and industrial areas are significantly enhanced. The magnetic susceptibility (χlf) of the soil profiles in the agricultural field, residential area, traffic green belt, and Shidongkou and Wujiang industrial Parks, are 26.5×10-8 m3 kg-1, 60.5×10-8 m3 kg-1, 80.4×10-8 m3 kg-1, 108×10-8m3 kg-1, and 269×10-8 m3 kg-1 on average, respectively. Correspondingly, the content of heavy metals in the agricultural soil is relatively lower with the average of Cr, Cu, Pb, Zn, Cd, Ni, Co, Mn, and Fe being 73.3 mg kg-1, 19.2 mg kg-1, 16.6 mg kg-1, 50.4 mg kg-1, 0.599 mg kg-1, 34.9 mg kg-1, 19.8 mg kg-1, 0.792 g kg-1, and 33.0 g kg-1, respectively; that in the traffic and residential soils is increased; that in the industrial soils is the highest. For example, the content of Cr, Cu, Pb, Zn, Cd, and Mn in the soil of the Wusong industrial Park is 455 mg kg-1, 30.3 mg kg-1, 73.2 mg kg-1, 149 mg kg-1, 1.44 mg kg-1, and 1.67 g kg-1 on average, which is 6.01, 1.29, 3.44, 1.97, 4.11, and 2.0 times the magnetic background of the Shanghai soils.

The magnetic characteristics and heavy metal contents of the soil profiles in the different areas show significant differences in vertical distribution. The χlf and heavy metal content in the surface of the agricultural soil profiles are slightly higher; but below 30 cm, it rapidly decreases and tends to be stable. There are large industrial parks or other pollution sources around the agricultural area. The studied agricultural field is located at the downwind direction of Shanghai Shidongkou Power Plant, and the increase of heavy metals in the surface layer may be related to the deposition of pollutants from industrial sources.

The χlf and heavy metal content fluctuate significantly in the middle and lower layers of the soil profiles in the greening belt of traffic lines and residential area. The fluctuations in the residential soils may be due to the historical disturbance, when the polluted soil in the area was turned over and buried in the lower layer; and these in the greening belt may be related to the planting of vegetation, which will turn the polluted soil exposed on the surface into the lower layer.

The χlf and heavy metal content of the industrial soil profiles in the Shidongkou Industrial Parks and the Wusong Industrial Parks are very high in the surface layers (0-5 cm), and greatly fluctuate in the middle and lower layers. The abnormal increase of χlf in the surface is related to the deposition of a large number of magnetic particles carried by suspended particles such as coal-fired fly ash and steelmaking dust from power plants in the region, while the large fluctuations in the middle and lower layers are also related to the invasion of artificial pollutants in the historical period.

The χlf value of the agricultural soils is significantly positively correlated with the content of Cr, Cu, Pb, Ni, and Fe ($p<0.05$); that in the traffic soils is significantly positively correlated with Cu, Pb, and Zn; that the industrial soils is extremely significantly positively correlated with a variety of heavy metals ($p<0.01$), with high correlation coefficients; however, there are no such correlations in the residential soils. Nevertheless, the χlf of all soil samples in this study is significantly positively correlated with the content of Cr, Cu, Pb, Z, Cd, Ni, Co, Mn, and Fe ($p<0.05$). This suggests that χlf in the urban/industrial soils in Shanghai has a good indicative significance for the accumulation of heavy metals.

# Magnetic Characteristics of Typical Soils in Guangdong Province and Their Responses to Parent Materials and Land Use

**Lu Ying Zhuang ZI-kun Lai Zhi-ming Cui Luo-xiao**

**ABSTRACT**

Soil magnetic properties serve as vital proxies for understanding pedogenic processes and environmental evolution. This study investigated 199 typical soil profiles in Guangdong Province, characterized by intense weathering and diverse parent materials. Key parameters, including low- and high-frequency magnetic susceptibility (Xlf、Xhf), frequency-dependent susceptibility (Xfd), and preliminary remanence data, were measured to analyze spatial distribution and controlling factors. The main findings are as follows: Parent material is the primary factor determining the background magnetic intensity. Significant differences in Xlf were observed among soils derived from different parent materials, with mean values decreasing in the order: Basalt (424.92×10-8m3/kg)≫ Sandstone (36.51×10-8m3/kg)≈ Granite (36.29×10-8m3/kg)> Sediments (28.65×10-8=m3/kg).The extremely high magnetic background of basalt-derived soils reflects the substantial contribution of primary ferrimagnetic minerals from basic rocks. Land-use patterns significantly modified the magnetic characteristics of topsoils. Results showed that the mean Xlf of forest topsoils （50.60×10-8m3/kg） was significantly higher than that of paddy soils （16.63×10-8m3/kg）. This indicates that natural pedogenesis leads to magnetic enhancement, whereas long-term flooding and reductive conditions (gleying) in paddy fields cause the reductive dissolution of magnetic minerals, resulting in a marked decrease in intensity. A positive correlation between Xfd% and Xlf suggests the widespread presence of pedogenic superparamagnetic (SP) and single-domain (SD) grains in Guangdong soils. Preliminary analysis indicates that ferrimagnetic minerals are the dominant carriers of soil magnetism in the study area. The spatial distribution of soil magnetic susceptibility in Guangdong exhibits strong lithogenic inheritance and is profoundly modified by anthropogenic hydro-pedogenesis. This study provides a scientific baseline for soil genesis and environmental assessment in South China.

**ABSTRACT**

Soils sustain life by filtering water, cycling nutrients, supporting biodiversity, and enabling food production, and thus is a fundamental resource for advancing the UN Sustainable Development Goals. The ecosystem services provided by the soil are fundamentally dependent on its structure, which defines the very nature of soil, mediating the interactions among air, water, minerals, and biota that underpin all soil-derived ecosystem services. Yet intensive management practices, such as frequent tillage, heavy machinery, livestock treading, and deforestation threaten the critical soil structure. This potentially jeopardises food security, increases greenhouse gas emissions, accelerates erosion, and impairs water storage and quality. Such impacts are likely to amplify under climate change.

The degradation of soil structure and associated losses in soil functions and ecosystem services are related to soil structural vulnerability (SSV). Current SSV assessments are based on static properties that poorly predict the soil functions needed to forecast changes in ecosystem services, both positive and negative, including plant production and greenhouse gas emissions We propose that SSV, analogous to human disease vulnerability, should be defined by the soil's ability to sustain and recover its functions and services under external pressures.

Using literature review, data synthesis, our controlled experiments and modelling, we demonstrate how dynamic functional properties of contrasting soil types respond to compaction, and how these responses influence plant productivity and $N_2O$ emissions. We highlight the need to assess SSV through the responses of dynamic soil functions and their consequences for ecosystem services. We advocate for a functional and service-oriented soil management framework that incorporates SSV into adaptive, outcome-focused, decision-making tools. Such a system is essential for enhancing soil resilience and safeguarding ecosystem services under changing climates and land uses.

# Viral Diversity in Different Types of Purplish Soils

**WEI Xieluyao[1]*, TIAN Xianrui[1], Gu Yunfu[1]** (Corresponding author)
[1]*College of Resources, Sichuan Agricultural University, Chengdu 611130, China*
*894226861@qq.com

**ABSTRACT**

Purplish soils are a typical agricultural soil type in the upper Yangtze River region, and differences among soil types significantly affect soil quality and nutrient cycling processes. As key regulators of microbial metabolism and nutrient transformation, viruses play important ecological roles. However, their community characteristics and functional differentiation across different types of purplish soils remain poorly understood. This study focused on three typical purplish soils from Sichuan Province: acid (AC), neutral (NE), and alkaline (AL) types. Using high-throughput viromic sequencing, we systematically analyzed viral diversity, metabolic functional differences, and virus–host interaction patterns across different soil pH conditions. Viral diversity was highest in AL soils and lowest in NE soils. However, NE soils had the greatest abundance of viral genes associated with carbon, nitrogen, and phosphorus metabolism, and showed the most complete pathway coverage, including key metabolic enzymes such as porA, ack/acs, and ppx/ppa. The predicted host community in NE soils was taxonomically diverse, including Cyanobacteriota, Actinomycetota, and Pseudomonadota, with strong potential for carbon fixation and extracellular polysaccharide degradation. In AL soils, viral functions were enriched in key genes like phoB/R and amoA, suggesting roles in phosphorus acquisition/regulation and nitrification, with hosts such as Candidatus Dadabacteria and Verrucomicrobiota. In AC soils, viruses were enriched in gcd and pstC/A genes related to high-affinity inorganic phosphorus solubilization and uptake, suggesting that viruses may enhance phosphorus acquisition under acidic, nutrient-limited conditions.These results demonstrate that viruses and their hosts form distinct interaction networks in different purplish soil types, reflecting their regulatory potential in nutrient utilization strategies. This mechanistic understanding offers theoretical guidance for improving soil quality and optimizing fertilization practices based on microbe–virus interactions.

# Silicon cycling model and its roles on soil evolution in a subtropical critical zone

**Jin-Ling Yang**[1, 2*], **Gan-Lin Zhang**[1, 2]

[1] *Institute of Soil Science, Chinese Academy of Sciences, Nanjing, China*

[2] *University of Chinese Academy of Sciences, Beijing, China*

*E-mail Address: jlyang@issas.ac.cn

**ABSTRACT**

Silicon (Si) is one of the most important elements of the Earth surface. Biogeochemical cycling of Si influences the processes of weathering, leaching, plant uptake and transformation. However, the roles and contributions of Si translocation and transformation on soil genesis and evolution in subtropical areas with ample weatherable silicates is largely unknown in the critical zone.

A typical forested watershed and two forest-agriculture watersheds located in southern Anhui Province, subtropical China were selected to study Si cycling and soil evolution. The main crop was rice and the main forests pecies were pine, fir, chestnut, bamboo, shrubs and grass. The main soil types are Lithic Udorthents, Lithic Dystrudepts and Typic Epiaquepts derived from granite. The rock and soil physical, chemical and mineralogical characteristics were measured. Si and base cations cycling amount among rock, soil, plant, water and atmosphere were determined.

High Si uptake by plant significantly increased the mineral weathering and soil formation rates. Therefore, the weathering and soil formation rates estimated from net output by stream without consideration of the effects of plant would be greatly underestimated. Desilification and resilification coexisted in the subtropical area during soil formation. Plant growth was very important to Si cycling, not only increased the primary mineral weathering, but also redistributed Si in the soil profile and enriched Si in the surface soil. Plant species greatly affect the amount of Si cycling and phytolith-Si concentrations in soil. High Si accumulators could assimilate and return more Si than low accumulators, and also enrich more biological Si in the surface soil.

Therefore, Biological Si cycling plays an important yet secondary role in the subtropical soil development. Silicate weathering dominates Si flux between soil-plant system. Agricultural activities and plant species affect Si translocation and redistribution in soils. Different plants represented soil desilication or resilication according to its ability in cycling Si.

**ABSTRACT**

Soil structure built from aggregates and mineral–organic bonds controls water movement and biogeochemical processes in the Earth's Critical Zone. Scalable approaches for quantifying these properties are needed to assess ecosystem resilience under changing environmental conditions. This study compares near-infrared (NIR) and mid-infrared (MIR) spectroscopy for predicting key structural, hydraulic, and chemical soil properties using 1,976 samples from the Open Soil Spectral Library, collected primarily from the United States. NIR spectra were acquired using a Neospectra portable spectrometer, while MIR spectra were collected using Bruker Alpha II and Bruker Vertex 70 instruments equipped with an HTS-XT attachment. Baseline correction and standard normal variate preprocessing were applied to reduce baseline shifts and spectral variability. Models trained on NIR spectra showed strong performance ($R^2 \approx 0.80–0.95$) only for total sulfur and $CaCO_3$, and moderate accuracy ($R^2 \approx 0.50–0.80$) for organic carbon, total carbon, cation exchange capacity, potassium, magnesium, pH, and clay. NIR struggled with structure-controlled properties such as field capacity and permanent wilting point, where most models produced $R^2 < 0.50$. In contrast, MIR spectroscopy achieved consistently higher accuracy across nearly all soil properties. MIR produced $R^2 \approx 0.80–0.98$ for organic carbon, total carbon, total sulfur, $CaCO_3$, cation exchange capacity, pH, clay, sand, and permanent wilting point, with moderate performance ($R^2 \approx 0.50–0.80$) for total nitrogen, electrical conductivity, bulk density, and field capacity. These gains reflect MIR's ability to resolve absorptions linked to clay minerals, carbon functional groups, and microaggregate features—key drivers of water retention and pore continuity. Across both NIR and MIR regions, Categorical Boosting, Random Forest, Cubist, Artificial Neural Networks, Least Absolute Shrinkage and Selection Operator, Elastic Net Regression, Ridge Regression, and Partial Least Squares Regression performed well, with the strongest results in the MIR region. These models captured mineralogical, structural, and biogeochemical signals more effectively, improving predictions of soil structural, hydraulic, and chemical properties. Overall, MIR provides a more robust platform for quantifying soil structural, hydrological, and biogeochemical functioning, while NIR offers a rapid and portable alternative where moderate accuracy is acceptable. Future work should examine whether spectroscopy can reliably predict biological soil indicators—such as microbial biomass, enzymatic activity, and labile carbon fractions—to integrate physical, chemical, and biological dimensions of Critical Zone soil health.

*shimelesdamene@yahoo.com, shimeles.damene@aau.edu.et*

**ABSTRACT**

Land use and land cover (LULC) changes, driven by policy interventions and shifting socioeconomic activities, have raised increasing environmental concerns and contributed to land degradation in Ethiopia's lowlands. Over the past three to four decades, these changes have altered landscape structures, including the Lower Alwearo watershed, often resulted unintended ecological consequences, such as declining soil quality. Therefore, the objective of this study was to assess the effect of LULC changes on soil health using a set of scientifically validated soil quality indicators. A total of 131 disturbed and 58 undisturbed soil samples were collected across different LULC types and analyzed for key physicochemical properties. The samples were analyzed for standard attributes in the laboratory, and the results were subjected to Principal Component Analysis (PCA) to identify a Minimum Data Set (MDS) of the most influential soil indicators, which informed the construction of a Soil Quality Index (SQI) using a weighted additive approach. Statistical analysis showed a significant difference in soil quality indicators across LULC types. Among the LULC types, there is a clear trend in the variation of SQI values decreasing from natural forests and grasslands (1.0) to mechanized farmlands (0.86), largely due to intensive tillage and nutrient depletion, whereas smallholder farmlands benefit from minimal disturbance and traditional conservation practices. Woody grasslands showed moderate soil quality (SQI = 0.90), reflecting the effects of biomass extraction and grazing pressure. Seven key soil quality indicators, such as total nitrogen, cation exchange capacity, exchangeable calcium, exchangeable magnesium, available phosphorus, and bulk density were identified as critical metrics for soil quality monitoring in the watershed. Despite widespread land conversion, overall soil quality remains relatively high, partly due to under-utilization of cleared land and continued reliance on indigenous land management practices. The study recommends integrating these indicators into land use monitoring frameworks to guide sustainable land management. It further emphasizes the importance of conservation-based agriculture, regular soil assessment, and the incorporation of indigenous conservation practices into policy design to ensure environmental resilience and agricultural productivity in Ethiopia's lowland ecosystems and beyond.

**ABSTRACT**

Large clods with some centimeters are formed by tillage in a clayey paddy field. As the clod size becomes larger, the water vapor movement is strongly enhanced due to wind, while the unsaturated hydraulic conductivity remains almost unchanged. These characteristic water vapor and liquid water movement in the soil layer composed of clods (SLC) results from the arrangement of clods and inter-clod pore spaces. However, the effect of clod size on these soil structure still remains unclear. In this study, we analyzed the soil structure of SLC with different diameters using X-ray CT images.

We sampled four kinds of SLC from the surface of paddy fields in triplicate using the PVC column with a diameter of 15.4 cm and a height of 9.7 cm just after tillage. The mean clod diameters (MCDs) of these SLCs were 0.8, 2.0, 2.4, 4.1 cm. The SLCs were scanned by the industrial X-ray CT scanner with a tube voltage of 150 kV. The obtained projections were reconstructed to 3D volume and then converted to the 16-bit image stacks with a image resolution of 94.4 or 95.0 µm. The image analysis was conducted using SoilJ (Koestel, 2017), which is the plugin of Fiji. The median filter and unsharp mask filter were applied to the image stacks. The region of interest was designated as the inside of column wall, bottom of the column, and 26 mm below the top of the column. The artifact of beam-hardening was corrected and the gray values of each image slice were standardized. And then, Otsu segmentation method was applied to separate the clods and inter-clod pore spaces. Using the function of "PoreSpaceAnalyzer" in SoilJ, following properties were obtained: porosity and averaged diameter for inter-clod pore spaces; profile of clod fraction and critical diameter for clods; connectivity and percolating fraction for both.

As a result, for the inter-clod pore spaces, the connectivity and percolating fraction was almost unity in all SLC. As the MCD increased, while the porosity (0.31-0.43) slightly decreased, the averaged dimeter markedly increased from 1.1 to 8.0 mm. These results indicated that the enhancement of water vapor movement by wind can be influenced by the size of inter-clod pores. On the other hand, for the clods, the connectivity and percolating fraction was also almost unity in all SLC. As the MCD increased, while the critical diameter markedly increased from 1.0 to 13.1 mm, the clod fraction was close across SLCs. These results indicated that the unsaturated liquid water movement can be prescribed by the clod fraction of cross-sectional area in SLC.

**ABSTRACT**

Soil structure fundamentally regulates biotic processes and ecosystem functioning in the Earth's Critical Zone. Organic inputs, together with the configuration of pores and biopores, control hydrological and aeration processes and govern the spatial availability of organic substrates, thereby shaping microbial activity, soil fauna niches, and root growth. However, the extent to which microstructural development shapes carbon cycling and soil food-web dynamics across contrasting land-use systems and under the future climatic scenario remains insufficiently understood. Using the Global Change Experimental Facility, which includes two annual croplands and three perennial grasslands under ambient and future climate scenarios, we integrated deep-learning-based X-ray CT segmentation, biogeochemical measurements, and soil nematode assessments to quantify microstructure–function linkages in soils.

Grasslands exhibited persistently higher volume fraction of particulate organic matter (POM), biopore, and root-derived structures due to continuous root inputs and the absence of tillage, leading to the formation of stable microstructure characteristic within 4–5 years. Croplands, in contrast, showed greater proportions of fresh roots, but reduced decaying roots and biopores, reflecting seasonal growth pulses and structural disturbance by plowing. Microbial biomass carbon and extractable organic carbon were consistently higher in grasslands, whereas total soil organic carbon displayed a slower degree of divergence among land-use systems. Climate treatments mainly influenced heterotrophic respiration through soil moisture, while exerting negligible effects on microstructure or carbon fractions. Across systems, POM volume, rather than pore structure, was the dominant predictor of carbon mineralization, probably because aeration of microbial hotspots was not limiting.

By explicitly linking microstructure to soil biota, we found that nematode communities responded strongly to land use and seasonality but only weakly to climate manipulation. In cropland soils, nematode abundance and composition were tightly coupled to microhabitat properties such as nematode-specific porosity, pore connectivity, and POM volume, indicating a strong bottom-up regulation by resource accessibility. In grasslands, however, nematode communities were largely decoupled from measurable structural and biochemical properties and instead exhibited stronger and more complex co-occurrence networks among nematode taxa, which may reflect higher functional redundancy, shared environmental pReferences, or stronger biotic interactions. Climate effects on nematodes were subtle, varied with season and land use, and were not mediated by microhabitat changes.

Together, these findings demonstrate that soil microstructure serves as a central organizing constraint on carbon cycling and nematode community structure, but its regulatory strength depends strongly on land-use-driven resource inputs.

# Straw incorporation mitigates polyethylene residual film-induced suppression of fungal necromass

**Conghui Liu[1], Xiaohong Tian[1*], Xiangtian Meng[1], Hanyu Guo[1]**

[1] *College of Natural Resources and Environment, Northwest A&F University, Yangling, Shaanxi, China*

*Xiaohong Tian, Email: txhong@nwafu.edu.cn

**ABSTRACT**

In arid and semi-arid farmlands, polyethylene residual film (PRF) poses a serious threat to soil ecological functioning. In agricultural practices, PRF frequently coexists with straw. However, the mechanism underlying their synergistic effects on soil organic carbon (SOC) turnover remains unclear. To investigate this, 13C stable isotope tracing, 16S/ITS absolute quantitative sequencing, and amino sugar biomarker analysis were employed to elucidate the mechanisms of SOC turnover under PRF addition alone [0.06% (R1) and 0.12% (R2), w/w] and in coexistence with straw [1.2% (S), w/w]. PRF alone (R1/R2) significantly suppressed fungal abundance, reducing fungal ITS rRNA gene copy numbers by 21.46% and 21.94%, respectively, which in turn decreased fungal necromass carbon by 12.86% and 3.32%. In contrast, the coexistence of PRF and straw (SR1/SR2) generated heterogeneous microsites through the combined effects of PRF hydrophobicity and straw porosity. This enhanced the priming effect and promoted straw decomposition. Meanwhile, these changes were accompanied by 8.94% and 3.41% increases in fungal abundance and fungal necromass carbon, respectively, ultimately stabilizing SOC. Notably, under SR2, physical degradation and weak carbonyl peaks indicated early-stage plastic degradation. Overall, straw alleviates PRF-induced fungal suppression, transforms PRF from pollutant to structural modifier, and reshapes microbial necromass carbon pathways, promoting SOC retention.

## ABSTRACT

In arid mountain ecosystems, geodiversity, including microtopography, slope orientation, and geomorphological complexity, plays a fundamental role in regulating the redistribution of water and nutrients. These terrain-driven processes shape vegetation patterns and contribute to the formation of “fertile islands”: discrete shrub patches that enhance local soil properties and ecosystem functioning. In the southern Tarbagatai Mountains of southeastern Kazakhstan, the endemic wild almond (Prunus ledebouriana) forms persistent shrub communities between 600 and 1200 m a.s.l., contributing to landscape-scale vegetation mosaics and modifying soil conditions.

This study investigates whether topographic variables (as proxies for geodiversity) or soil properties better explain (i) the spatial dominance of almond shrub patches and (ii) their functional performance. We surveyed 56 plots distributed along elevation and terrain-position gradients within a typical valley on the southern slope of the Tarbagatai range, where P. ledebouriana naturally occurs. To explore the relationships between environmental variables and shrub performance, we applied regression-based analyses supported by model selection criteria.

Our results show that among all tested variables, topographic position, particularly “distance from the top” was the strongest predictor of shrub cover ($p < 0.001$). In contrast, average shrub height was more strongly associated with soil properties, especially electrical conductivity ($p = 0.047$), suggesting that salinity influences structural development. Lithological variation, including differences among colluvium, slope deposits, loess, and eluvium, also affected shrub height, with eluvial substrates associated with reduced stature ($p= 0.027$).

Functional leaf traits followed similar patterns. Chlorophyll content was primarily influenced by soil porosity ($p = 0.035$), with copper concentration further improving model performance and potentially acting as a limiting micronutrient in some sites. In contrast, the leaf N:P ratio was significantly related to topographic position, with higher values observed downslope ($p < 0.001$), indicating slope-driven variation in nutrient limitation regimes.

To synthesise these findings, we developed a Shrub Health Index (SHI) integrating morphological and physiological traits. The stronger association of the SHI with soil characteristics than with topographic variables supports a dual control framework, in which geodiversity governs the spatial establishment of almond shrubs, while soil properties regulate their functional performance. These insights advance our understanding of how intersecting terrain and soil factors shape perennial vegetation structure in arid mountain systems, with direct implications for predicting ecosystem responses to increasing aridity.

## ABSTRACT

Knowledge of soil structure and hydraulic properties is essential for hydrological modeling and agricultural water management. These properties are well known to exhibit substantial temporal variability in response to climatic conditions, biological activity, and anthropogenic interventions. For instance, tillage can temporarily increase macroporosity, near-saturated hydraulic conductivity, and water infiltration, although these effects typically diminish over time. Meanwhile, management practices such as incorporating cover crops into rotations and applying manure have been shown to enhance soil structural stability, improve water infiltration, and increase soil water-holding capacity. However, quantitative assessments on the short-term dynamics of soil hydraulic properties under reduced tillage systems remain limited. To address this knowledge gap, this study aimed to frequently quantify soil hydraulic properties and pore size distribution throughout the winter cover crop and subsequent corn seasons under reduced tillage with cover crop and manure treatments in the humid Southeast United States. Hydraulic conductivity at multiple tensions, soil water retention curves (SWRC), bulk density (BD), and pore size distributions (PoSD) were measured on undisturbed soil samples collected at five key sampling dates, including post-tillage, mid-cover crop season, pre-cover crop termination, mid-corn season, and pre-corn harvest. The results provide valuable insights for improving agricultural water management in humid regions and highlight the importance of accounting for temporal variability of soil hydraulic properties in hydrological models.

# Multifractal scaling of soil particle size distribution validates aggregate stability and pedogenic processes along a semi-arid erosional gradient.

## ABSTRACT

Understanding soil structure is essential for evaluating land degradation, especially in vulnerable semi-arid regions. This study assessed the efficacy of fractal and multifractal parameters of the particle-size distribution (PSD) as process-sensitive indicators of soil structural stability and pedogenesis. Here, 14 soil horizons from three profiles (P1, P2, P3) situated along a semi-arid erosional gradient were examined, assessing essential soil properties including soil organic carbon, electrical conductivity (EC), mean weight diameter (MWD) and water-stable soil aggregates (WSA) and computing an extensive array of fractal descriptors (Df, D1, D2, Δα). The findings revealed robust, physically significant correlations between the fractal parameters and soil functional properties. The single-fractal fragmentation dimension (Df) had a strong link to aggregate stability. This showed that finer soil textures (higher Df) were linked to more stable aggregates (higher MWD, r=0.67; lower WSA, r=-0.62). This substantiates Df as a reliable metric for the principal textural determinants of soil stability, wherein fine particles serve as essential binding agents. The multifractal analysis also gave a lot of new information about how pedogenic pathways work. The generalised dimension spectra (D(q) vs. q) acted as unique "fingerprints" for each of the soil profile, clearly separating classic illuviation (P1, with a simple eluviated layer over a highly complex argillic subsoil), geological stratification (P3, defined by an unusual, coarse-textured sandy layer), and complex accumulation processes (P2). There was a positive correlation (r=0.55) between multifractal heterogeneity (Δα) and electrical conductivity (EC). This quantitatively linked the complexity of soil structure to landscape-scale accumulation processes along the semi-arid erosional gradient. In conclusion, this integrated fractal/multifractal methodology offers a robust, quantitative framework. It effectively correlates PSD geometry with soil function and identifies distinct pedogenic histories, demonstrating that these parameters are highly sensitive indicators of soil stability and development in intricate semi-arid landscapes.

*E-mail address of Presenting Author: zjxie@jxau.edu.cn

**ABSTRACT**

Rice straw biochar (RSB) and milk vetch (MV) are increasingly served as ideal soil amendments in promoting rice production and soil health in paddy fields. However, the mechanism of how annually applying RSB and MV, along with reduced N fertilizer, influenced rice productivity and soil carbon (C), nitrogen (N) stocks are elusive. A field experiment, with four treatments: 100% N fertilizer (N100), 80% N fertilizer along with RSB (N80B), MV (N80M), RSB+MV (N80BM) respectively, was conducted to evaluate the impacts on rice performances, soil aggregates and C, N stocks. Compared to N100 plots, N80B, N80M and N80BM obtained more grain yields, straw and shoot biomasses, and especially, the N80BM strikingly increased these items by 11.2%, 10.0% and 10.6%, respectively. The highest soil C, N stock rates were observed in N80BM, then soil organic C (SOCs) and total N stocks (TNs) were 5.42% and 6.92% higher than N100. Moreover, RSB and/or MV along with reduced N fertilizer prominently increased the mean weight diameter, geometric mean diameter and contents of aggregates at >0.25 mm by 7.14%-15.7%, 29.3%-58.1% and 7.92%-11.8%, while decreased content of silt-clay particle by 39.6%-62.9% vs N100 plots, respectively. The enrichments of C and N were mainly obtained in mega- and macro-aggregates, leading to noticeably enhancing the contents and contribution rates of aggregate-associated C, N at >0.25 mm in RSB and/or MV plots, and N80BM amplified these benefits. Pearson correlation analysis revealed dramatical positive relations among rice yield, TNs, SOCs and soil aggregate stability, and random forest model further explained 49.6%-75.9% of variations for rice yield, SOCs and TNs. Hence, results indicated that combining RSB with MV along with reduced N fertilizer is a promising strategy in promoting rice productivity, soil health, and greenhouse gas emission risks reduction, which have great potential in covering the food security and “dual carbon” objectives in China.

**ABSTRACT**

Organic fertilizers can partly substitute mineral fertilizers in addressing land degradation challenges, through their effectiveness varies by type. A global-scale meta-analysis of 422 pairs field experiments revealed that animal manure increases soil fertility more effectively than plant residues, especially on acidic ones. This difference is largely attributed to the greater microbial growth and activity stimulated by animal manure. Microorganisms, as one of the most abundant biological and functional groups on Earth, are increasingly use as innovatory productive forces in organic wastes utilization. For example, Acinetobacter and Aspergillus niger have been identified as high-efficiency bioinoculants that accelerate the composting of plant residues such as straw. They enhance organic matter degradation and nutrients (e.g., phosphorus) release, thereby narrowing the gap in soil fertility increases between applications of plant residues and of animal manure. A 45-day pot experiment demonstrated that combining straw with these microorganisms increased ryegrass (Lolium perenne L.) growth by 79.7% and phosphorus uptake by 102.5%. Furthermore, we also found some copiotrophic manure-borne bacteria can colonize soils for several months and improve nutrient cycling by regulating enzymatic stoichiometry. Cytophaga, as one of them, survives in 7 types of soils irrespective of manure application amount and frequency. Its colonization relies on the superior competition driving by interspecies antagonism over resident soil microorganisms. Together with novel perspective of “community coalescence” by which positively affecting ecosystem functions, engineering tailored microbial consortia for different organic fertilizers is expected to leverage microbiomes to promote sustainable agriculture.

# Size – Specific Effects of Intra-Aggregate Pore Size Distribution on Soil Aggregate Stability

**Chaonan Liu[1], Miaomiao Wang[1], Yang Zhang[1], Enheng Wang[1*]**

*[1] Collage of Forestry , Northeast Forestry University, Harbin, China*

*E-mail: erxin222@163.com

**ABSTRACT**

Soil aggregate stability is crucial for maintaining soil structural integrity and biochemical functions. However, the mechanisms by which intra-aggregate pore size distribution (PSD) influences stability across different aggregate size classes remain unclear. We measured intra-aggregate pore volumes using mercury intrusion porosimetry (MIP) and quantified aggregate water stability using the percentage of aggregate destruction (PAD) in 2–5, 1–2, and 0.25–1 mm aggregates collected from Mollisols after 0, 30, 60, and 90 years of traditional cultivation in Northeast China. We further evaluated the relative contributions of PSD, soil organic carbon (SOC), and soil texture (ST) to aggregate stability. The results showed that: (1) volumes of intra-aggregate pores decreased with increasing cultivation duration; (2) PAD increased from 0 to 30 years and then declined from 30 to 90 years; (3) pores in the 5–90 μm range were significantly negatively correlated with PAD across aggregate sizes, underscoring their pivotal role in maintaining aggregate stability; and (4) PLS-SEM analysis revealed that PSD was the primary driver of stability in M-sized aggregates, whereas SOC fractions were more influential in the other size classes. These findings provide mechanistic insights into soil structure and aggregate stability and may inform assessments of soil degradation, development of restoration strategies, and overall soil health.

# Spatial heterogeneity shapes enantioselective horizontal transfer of antibiotic resistance genes by pydiflumetofen in agricultural soils

**ABSTRACT**

Chiral pesticides are widely used in agriculture, yet their enantioselective impacts on antibiotic resistance gene (ARG) dissemination under spatially heterogeneous soil conditions remain unclear. Here, pydiflumetofen (PYD), a newly introduced chiral amide fungicide, was selected to investigate how its enantiomers regulate ARG horizontal transfer in farmland soils. A cluster-resolved soil microcosm mimicking heterogeneous pesticide distribution during field application was coupled with microfluidic in situ observations plus an intergeneric conjugation model to quantify enantioselective effects and mechanisms. PYD exposure induced a non-monotonic risk pattern, as total ARGs, mobile genetic elements (MGEs), and the health-risk index peaked in the intermediate-exposure band (Cluster 2) rather than in the highest-exposure band, suggesting that risk may not increase linearly with concentration. Compared with S-PYD, R-PYD more strongly enriched multidrug resistance–associated ARGs and increased ARG–MGE network connectivity within the identified hotspot, indicating higher dissemination potential. Microfluidic assays further confirmed that conjugation predominantly occurred at biofilm interfaces on microstructured surfaces and reached its maximum under intermediate exposure. Mechanistically, PYD enantiomers differentially promoted bacterial attachment and biofilm development while eliciting stronger oxidative stress and metabolic responses, collectively enhancing conjugation frequency. These findings demonstrate that spatial heterogeneity can markedly amplify enantiomer driven ARG transfer by PYD, providing a basis for spatially explicit risk assessment and safer management of chiral pesticide use in agricultural systems.

**ABSTRACT**

Global climate change, driven by rising atmospheric $CO_2$ concentrations, is increasing the frequency and duration of extreme weather events, such as droughts and heavy rainfalls. The implications of these changes for soil-plant interactions in managed grasslands remain poorly understood. To investigate the combined effects of increased $CO_2$ (+300 ppm) and elevated temperature (+3 °C), along with a 2-month summer drought, we conducted a study using undisturbed topsoil and subsoil samples from a 10-year climate change experiment (ClimGrass) in a submontane grassland in Gumpenstein, Austria. We hypothesize that elevated $CO_2$ and temperature will enhance above- and below-ground biomass, leading to increased root growth and a corresponding rise in soil porosity, particularly of the proportion of biogenic macropores, which is expected improve aeration and boost gas diffusion rates.

We analyzed potential changes in soil structure by scanning 66 undisturbed samples with a high-resolution x-ray computed tomography system (only topsoil). Additionally, we measured water retention curves and oxygen diffusion rates (single chamber method) at different matric potentials (- 60, - 150, - 300 hPa) for the topsoil and subsoil, to examine how potential changes in total porosity, pore size distribution and pore connectivity affect gas exchange from the soil to the atmosphere at different moisture levels. As was expected, first results indicate that elevated $CO_2$ led to a lower bulk density and a higher amount of macropores, which also caused gas diffusion rates to increase. The moderating effects of elevated temperatures and droughts will also be discussed.

# Evolution of SRO Fe oxides in soils along a paddy field chronosequence: A Fe isotope perspective

**Zhao Wang[1*] and Ganlin Zhang[1]**

*[1] State Key Laboratory of Soil and Sustainable Agriculture, Institute of Soil Science, Chinese Academy of Sciences, Nanjing, China*

*E-mail: eezwa@issas.ac.cn

**ABSTRACT**

Short-range-ordered (SRO) Fe oxides are highly reactive carriers for inorganic contaminants and key stabilizers of soil organic carbon, yet their formation and evolution under sustained redox oscillations in field soils remain poorly constrained. Here we track the evolution of SRO Fe oxides along a paddy soil chronosequence developed on Quaternary red clays by combining Fe stable isotopes, chemical extractions, and $^{57}$Fe Mössbauer spectroscopy. Mössbauer spectra and extractions show that paddy cultivation redistributes Fe from crystalline Fe oxides into SRO Fe phases, increasing the SRO Fe fraction in both short- and long-term paddy surface horizons and in deep horizons of the long-term paddy profile. Positive Fe isotope fractionation between soils and porewaters ($\Delta^{56}$Fesolid–porewater = 0.45–0.98‰) indicates systematic enrichment of heavy Fe in newly formed SRO Fe. In long-term paddy surface horizons, comparatively smaller $\Delta^{56}$Fesolid–porewater (0.45–0.79‰) together with similar $\Delta^{56}$Fesolid–colloid (0.35–0.91‰) point to a major contribution of ligand-complexed colloidal Fe on the precipitation of SRO Fe. In deeper horizons, larger $\Delta^{56}$Fesolid–porewater (0.73–0.98‰) consistent with $\Delta^{56}$Fesolid–aq (0.73–1.13‰) instead reflect direct reprecipitation of SRO Fe from a light, truly dissolved Fe pool. By integrating our data with published soil and wetland datasets, we identify a negative relationship between $\Delta^{56}$Fesolid–porewater and SRO Fe abundance across systems, with less positive fractionation associated with higher SRO Fe contents. These results demonstrate that Fe isotope fractionation, when coupled with spectroscopic and extraction-based approaches, is an effective tracer of SRO Fe formation and evolution in redox-dynamic soils, with implications for predicting soil carbon stabilization.

# Assessing Soil Function Loss in Traditional Gold Mining Landscapes UsingFunction-Based Soil Quality Indicator Models

**ABSTRACT**

Traditional gold mining (TGM) can significantly contribute to land degradation, but its specific effects on vital soil functions remain underexplored in many developing regions. This study investigated soil degradation caused by TGM in Tigray, Ethiopia, with objectives to: (1) identify sensitive soil quality indicators and use them to develop function-based Soil Quality Indices (SQI); (2) compare two nonlinear scoring methods, threshold-based and mean-based; and (3) assess the extent of degradation caused by TGM across different sites.

A total of 192 soil samples were collected from various slope positions, depths (0–30 cm, 30–60 cm), and land uses (mined vs. unmined) at three TGM-affected locations. Out of 30 potential indicators, 11 were selected through principal component analysis to represent buffering and detoxification, nutrient cycling, structural stability & erosion resistance, and water–air–solute movement soil functions. SQI scores showed clear declines in soil function due to mining, especially on upper slopes and deeper layers. Over 52% of mined soils were classified as very low SQI grades, with degradation indices reaching up to 80% in upper slopes. Significant impacts included heavy metal buildup (Hg, Cu, Fe), nutrient loss (CEC, $Mg^{2+}$, P), and poor soil structure & erosion resistance, explained by low mean weight diameter and SOC, along with imbalanced water-solute-air movement caused by high soil compaction, low moisture content, and dominant coarse texture in the mined soils. The threshold-based scoring method proved more sensitive (sensitivity index: 16.03) than the mean-based approach (5.07), more effectively identifying soil degradation patterns. These findings confirm that function-based SQIs are significant for monitoring TGM-related soil impacts and the importance of slope-specific post-mining restoration strategies. Combining SQI data with land management plans and emphasizing the threshold-based approach are recommended.

**Key words:** Detoxification, Erosion tolerance, Nutrient cycling, Structural stability, Soil quality grades

# Pore-Scale Insights into Water-Heat Coupling during Soil Thawing in the Black Soil Zone

**Jiayun Wang, Baoguo Li*, Hu Zhou**

*College of Land Science and Technology, China Agricultural University, Beijing 100193, China*

*E-mail Address of Presenting Author: libg@cau.edu.cn

**ABSTRACT**

Soil thawing is a complex multiphysics process governed by pore-scale heat–water transport pathways. Long-term tillage practices fundamentally reshape soil pore networks, yet how such structural alterations influence thaw progression at the pore scale remains insufficiently understood. To address this gap, we investigated two contrasting systems—No-Tillage (NT) and Ridge Tillage (RT)—by coupling X-ray computed tomography (CT)-derived pore geometries with enthalpy-based Lattice Boltzmann Method (LBM) simulations to explicitly resolve transient heat transfer, phase change, and meltwater flow. Simulation results reveal pronounced differences in thaw behavior between the two pore architectures. RT exhibits accelerated thaw progression, with liquid saturation increasing to approximately 0.27, compared with about 0.12 in NT over the same duration. Vertical temperature profiles indicate that rapid phase conversion in RT facilitates deeper heat penetration, whereas NT maintains a sharp near-surface thermal gradient due to the high latent heat demand associated with its denser pore matrix. Three-dimensional diagnostics further show that interconnected macropores in RT sustain buoyancy-driven meltwater convection, enhancing downward heat transport beyond purely conductive limits. In contrast, flow fields in NT remain weak and spatially confined, restricting heat transfer to slower conductive pathways. These results reveal that soil thawing is jointly controlled by local ice–water–solid phase configurations and tillage-induced pore topology, among which the ice–water–solid phase configurations govern latent heat consumption during melting, whereas the pore topology regulates heat redistribution through conductive and convective pathways. This pore-scale perspective provides a physical basis for observed variability in field-scale thaw rates and offers quantitative constraints for improving the representation of freeze–thaw processes in land-surface and agrohydrological models.

# Nonstationary response evolutionary mechanisms of aggregate binding agents in Quaternary red soils during 400 years of cultivation

## ABSTRACT

Understanding the aggregate evolution of Quaternary red soil (QRS) is critical for its rational utilization. Despite its importance, the regulatory mechanisms governing interactions between soil organic matter (SOM) and Fe oxides during QRS aggregate formation remain unclear. Here, the QRS pedons cultivated for 0, 5, 80, and 400 years were systematically investigated. A QRS chronological framework was then established by determining the uniformity of parent material and the reliability of relative age. Using a soil reconstruction approach, the temporal evolution of SOM, poorly crystalline iron oxides (Feo), crystalline iron oxides (Fec), and aggregate structure across cultivation periods were quantitatively analyzed. Results revealed nonstationary responses of SOM and Fe oxides to cultivation duration. With cultivation time, SOM content initially decreased (0.01–0.03 g 100 cm–3 at 5 years) before increasing (0.04–0.11 g 100 cm–3 at 80 and 400 years). While, Fe oxides exhibited inverse trends—initial increases (0.20–0.85 g 100 cm–3 at 5 and 80 years) followed by decreases (0.09–0.33 g 100 cm–3 at 400 years). The critical time threshold for organic/inorganic binding agent evolution was identified, and cultivated QRS aggregate formation was divided into three stages. Stage I (0–6 years): Fe oxides dominate as primary binding agents. Stage II (6–362 years): Co-dominance of Fe oxides and SOM. Stage III (>362 years): SOM replaces Fe oxides as principal binding agents. Under these temporal dynamics, aggregate progression occurred in both arable and argic horizons, though aggregation rates declined with cultivation time. In arable horizons, <0.053 mm silt and clay fractions (7.89–14.24 g 100 cm–3) continuously bound to 0.5–1 mm macroaggregates (13.26–21.32 g 100 cm–3), while 0.25–0.5 mm macroaggregates fragmented (3.73–15.18 g 100 cm–3). In argic horizons, macroaggregate size distributions shifted toward 2–5 mm (upper horizons, 26.36–28.26 g 100 cm–3) and 1–2 mm (middle-lower horizons, 11.45–22.65 g 100 cm–3) after 6 years. These findings elucidate the nonstationary mechanisms of aggregate formation in response to organic-inorganic binding agent evolution and provide novel chronological evidence to refine aggregate formation theories in soil science. The identified temporal thresholds and stage transitions offer critical insights for sustainable QRS management and soil classification frameworks.

**ABSTRACT**

Higher nitrate ($NO_3^-$) fluxes have frequently been observed in Oxisols than in Ultisols of tropical forests (Shibata et al., 2017), yet the mechanisms underlying this pattern remain poorly understood, particularly in Southeast Asia where both soil types often exhibit similarly strong acidity. Field-based flux measurements alone provide limited insight into the processes governing nitrogen transformations. This study therefore examined the controls on nitrification and $NO_3^-$ dynamics by directly comparing surface soils (0–5 cm) of Oxisols and Ultisols developed under comparable climatic and vegetation conditions in tropical forests of the Central Highlands, Vietnam. Surface soils from 10 Oxisol and 8 Ultisol sites were analyzed for physicochemical properties, soil aggregate size distribution, microbial community characteristics, and nitrogen transformation processes. Gross nitrification rates were determined using a 15N tracer incubation method. The abundance of ammonia-oxidizing archaea (AOA) and bacteria (AOB) was quantified by real-time PCR, and stable nitrogen isotope ratios (δ15N) of soils and litters were measured to infer dominant nitrogen loss pathways. Gross nitrification rates and gross $NO_3^-$ consumption rates tended to be higher in Oxisols than in Ultisols, although the differences were not statistically significant. Rate constants of gross nitrification did not differ between soil types, suggesting that observed variations in nitrification activity were largely attributable to differences in substrate availability rather than inherent soil-type effects. Oxisols exhibited significantly higher clay contents, accompanied by greater organic matter accumulation and higher $NH_4^+$ availability. Correspondingly, the abundance of AOA was significantly greater in Oxisols and showed strong positive correlations with total carbon, total nitrogen, and $NO_3^-$ concentrations, whereas AOB abundance was consistently low across both soil types. Soil physical structure further distinguished the two soil types. Oxisols were characterized by smaller mean weight diameters and higher proportions of 0.25–2 mm aggregates. This aggregate fraction was positively associated with AOA abundance, indicating that microscale physical environments, likely through enhanced aeration and permeability, contribute to favorable conditions for nitrification. Stable isotope signatures suggested that denitrification played a more important role in $NO_3^-$ consumption in Ultisols, whereas leaching losses were likely more pronounced in Oxisols. Taken together, these results indicate that enhanced $NO_3^-$ fluxes in Oxisols are regulated by an interplay of substrate supply, soil physical structure, and microbial community composition rather than soil type per se. The findings emphasize the importance of integrating biological and physical controls when interpreting nitrogen flux patterns in highly weathered tropical forest soils.

# Deep soil nitrate accumulation depends on the regolith structure and surface land management

Shunhua Yang[1*], Huayong Wu[1], Xiaodong Song[1], Jinling Yang[1] and Gan-Lin Zhang[1]

[1] *State Key Laboratory of Soil and Sustainable Agriculture, Institute of Soil Science, Chinese Academy of Sciences*

*E-mail: shyang@issas.ac.cn

**ABSTRACT**

Deep nitrate accumulation below 1 m threatens groundwater quality, yet studies predominantly focus on surface soils (<100 cm) or specific sites, lacking large-scale cross-regional comparisons. This study investigates the distribution and controls of deep nitrate accumulation across two critical agricultural zones: highly weathered subtropical red soils and the intensively managed black soil (Phaeozems and Chernozems) region of Northeast China, where such accumulation was previously undocumented. We analyzed inorganic nitrogen forms and regolith properties in multiple deep boreholes (up to 10 m in black soil sites; encompassing full regolith profiles in red soils) spanning climatic gradients (humid to semi-arid) and management histories (e.g., planting years of orchard/cropland).

Results reveal significant but distinct deep nitrate accumulation patterns. In the black soil region, substantial nitrate accumulation was found specifically in the semi-arid site (Lindian), peaking at 11.03 mg N $kg^{-1}$ at 3 m depth, with 70% of the large storage (459.65–1072.88 kg N $ha^{-1}$ to 10 m depth) located below 1 m. In contrast, the red soil region showed storage from 43.6 to 1116.3 kg $ha^{-1}$ within the weathered regolith, where 81% of nitrate was stored in reticulated red clay layers. A key finding across both regions is that deep nitrate accumulation is governed by the interplay between subsurface regolith structure (e.g., thickness, texture, clay layers) and surface processes (e.g., land use history, fertilization, hydrological pathways). In red soils, regolith thickness strongly correlated with nitrate storage ($R^2$=0.43), and all accumulation parameters (except peak depth) increased with planting years. In black soils, regolith properties (clay, silt, sand, pH) were crucial in reshaping nitrate vertical patterns, with notable spatial variability: one site showed deep ammonium instead of nitrate accumulation, and another showed no accumulation, highlighting climate-management-regolith interactions.

We conclude that the paradigm of surface-focused nitrate management is insufficient. The presence of deep nitrate pools, whether in the reticulated clay of red soils or the subsoil of black soils, necessitates a regolith-centric perspective. Identifying regions vulnerable to high accumulation requires understanding how local management interacts with the specific deep regolith architecture and climatic context to mitigate groundwater pollution risks.(Yang et al., 2020a; Yang et al., 2020b; Yang et al., 2024; Yang et al., 2026)

**ABSTRACT**

Soil carbon sequestration is essential for maintaining soil fertility in agricultural systems and mitigating climate change. Soil pore structure could regulate soil carbon mineralization by controlling gas diffusion and the physical accessibility of organic substrates within the soil matrix. However, the mechanistic links between the temporal and spatial dynamics of soil pore structure and soil carbon emissions remain insufficiently understood, limiting the development of effective soil management strategies for sustainable agroecosystems. The objective of this study is to elucidate how temporal and vertical variations in pore-scale soil structure regulate soil carbon mineralization in a corn cropping system developed on yellow-brown soil in Anhui Province, China. We quantified three-dimensional soil pore structure characteristics, including pore size distribution, connectivity and spatial heterogeneity across key corn growth stages and soil depths using X-ray computed tomography combined with digital image analysis and geostatistical methods. Soil carbon mineralization rates were measured concurrently to assess their relationships with dynamic structural attributes. The results reveal pronounced seasonal and vertical variability in soil pore architecture during the corn growing season, with changes in pore connectivity, complexity and pore size distribution closely associated with variations in carbon mineralization rates. These findings demonstrate that dynamic pore-scale structural organization constitutes an important physical regulatory pathway linking soil structure to carbon cycling within the agricultural Critical Zone. This study advances a structure-based understanding of soil ecosystem functioning and provides a scientific basis for managing soil structure to regulate carbon emissions in agroecosystems.

# Stabilizing Soil Aggregates with Synthetic Polymers: A Wet Adhesion Perspective

**Gang Li**[1,*]

[1] *Research Centre for Resources Engineering towards Carbon Neutrality, The Hong Kong Polytechnic University, Hong Kong, China*

* 331869171@qq.com

**ABSTRACT**

Soil aggregates, as the fundamental structural units of soil, govern key soil functions through their formation, stabilization, and disintegration processes. Conventional understanding emphasizes the role of soil organic matter as a cementing agent that promotes soil aggregation, with aggregate stability largely attributed to this binding effect. However, existing research has primarily focused on interfacial interactions between soil particles and organic matter, overlooking the critical influence of the bulk properties of the binder—whether natural organic matter or synthetic polymers—on adhesion performance under wet conditions. From a materials science perspective, reliable wet adhesion requires two simultaneous criteria: strong interfacial interaction and sufficient mechanical toughness of the adhesive itself. Guided by wet adhesion design principles, this study re-examines the limited efficacy of common polymeric soil conditioners such as polyacrylamide (PAM), which suffers a drastic loss of mechanical toughness upon water uptake and thus fails to sustain long-term adhesion. We propose polyvinyl alcohol (PVA) as a superior polymeric binder. PVA not only forms strong hydrogen bonds with aluminosilicate mineral surfaces but also develops crystalline domains during drying, significantly enhancing its mechanical toughness. This synergistic mechanism—combining high interfacial energy with high bulk toughness—enables PVA to effectively bridge soil particles and construct highly stable aggregates. Experiments show that PVA-stabilized soil aggregates remain intact after one year of use under pot-culture conditions, with no observable disintegration (Figure 1), demonstrating significantly greater stabilizing efficiency than PAM. The resulting PVA-treated soil can be directly used as a potting medium, offering a sustainable alternative to non-renewable peat and reducing reliance on its extraction. Moreover, it holds promise for engineered soil structure management, as it enables direct control over aggregate size and distribution through machine-based fabrication. By integrating principles from materials science and soil science, this work presents an innovative paradigm for soil structure design and degraded land restoration.

Figure 1. PVA-treated soil aggregates remain intact after one year in pot culture, with no disintegration evident.

# Spatial distribution and influencing factors of the argillic horizon in the Northeast Black Soil Region

**Xi-Ting Zhang[1*], Zhong-Xiu Sun[1], Ying-Ying Jiang[2], and Si-Yi Duan[1]**

*[1] College of Land and Environment, Shenyang Agricultural University, Shenyang, Liaoning Province, China*

*[2] College of Life Engineering, Shenyang Institute of Technology, Shenfu Reform and Innovation Demonstration Zone, Shenyang, Liaoning Province, China*

* zhangxiting33@163.com

**ABSTRACT**

The argillic horizon serves as a critical structural support and hydrological regulator within soil profiles in Northeast China's Black Soil Region, with its spatial distribution profoundly influencing the productivity and ecological functions of black soil. This study aims to elucidate the spatial distribution characteristics of the argillic horizon in Northeast China's black soil region and quantitatively analyze its dominant environmental drivers. By integrating field survey sampling data and the historical soil survey data from 852 soil profile samples, combined with high-resolution environmental covariates (climate, topography, parent material, etc.), a random forest model was applied to predict the spatial distribution and characteristics of the argillic horizon.

Results indicate:The occurrence areas of the horizon were defined, primarily distributed in Jiamusi City, Harbin City, and Jixi City in Heilongjiang Province; Jilin City, Liaoyuan City, and Tonghua City in Jilin Province; Chaoyang City, Huludao City, and Dalian City in Liaoning Province; Chifeng City, Tongliao City, and Xing'an League in Inner Mongolia Autonomous Region. The total area of the horizon is approximately $14.7170\times10^4$ km², with distinct regional characteristics in its formation and distribution across different areas. Revealed the spatial distribution of the horizon characteristics: high-value depth zones are primarily concentrated in central-eastern Heilongjiang Province, central Jilin Province, and northeastern Liaoning Province, while low-value zones are mainly distributed in the southern part of the Eastern Four Leagues of Inner Mongolia and western Liaoning Province. High-value burial thickness zones are mainly concentrated in eastern Liaoning Province, while low-value zones are primarily distributed in the southern part of the Eastern Four Leagues of Inner Mongolia and northeastern Heilongjiang Province.

It clarifies that the formation of the horizon is influenced by multiple factors. Under the combined effects of climate, soil type, topography, biological factors, and parent material, the characteristics of the horizon exhibit distinct regional patterns across different areas. In areas with favorable climates and deep parent material, the horizon is thick; conversely, in regions such as shoulder slopes, steep slopes, and eroded terrace margins with harsh climatic conditions, the horizon is thin. This demonstrates the complexity and diversity of the horizon formation mechanism.

*gnsabimana1@gmail.com

**ABSTRACT**

Soil aggregate stability measurement is essential to determine soil health status under various conditions. The Mean Weight Diameter (MWD) is the most applied index to express aggregate stability particularly for wet and dry sieving. However, the MWD could generally present results affected by pre-stress aggregate size distribution when remained aggregates after stress are considered for calculation. Therefore, the objective of the present study was to eliminate the similarities between the MWD results and pre-stress aggregate size distribution, which largely affects treatments differentiation. Samples from 145-160 m (lower), 160–169 m (middle), and 169–175 m (upper) elevations differently affected by the Water Level Fluctuation in Three Gorges Reservoir (TGR) and control (>175 m) were exposed to wet shaking stress. Aggregates remained at each sieve opening, aggregates disintegrated/passed through the sieve opening, and small macroaggregates and microaggregates accumulated were recorded. These aggregates were used to determine and compare two indexes (1) using remained aggregates (MWD) and (2) using disintegrated/accumulated aggregates (MWDd/a) based on the differences among treatments. The results for both pre-stress aggregates and remained aggregates after stress were showed consistent significant differences ($p < 0.05$) between upper and control elevations. This gives indication that aggregates remained after stress strongly depend on pre-stress aggregate size distribution. As the MWD was calculated from remained aggregates, the identified difference between upper and control elevations for this index could also confirm its dependence to pre-stress aggregates distribution. Contrary, disintegrated and accumulated aggregates showed non-significant differences between upper and control elevations. This non-significant and significant differences between upper and control elevations for disintegrated and pre-stress aggregates suggest a non-dependence condition. Similarly, the upper and control elevations showed no significant differences in MWDd/a. This substantially informs that this index is independent from pre-stress aggregates distribution because it was entirely calculated from disintegrated aggregates. Higher aggregate stability was indicated by high MWD, with values ranging from 1.41 to 6.24 mm. On the other hand, higher stability was expressed by lower values of the MWDd/a, with the values varying between 3.87 and 0.5 mm. Overall, the present study evidenced the major advantage of considering the disintegrated/accumulated than remained aggregates in calculating unbiased MWD index for aggregate stability.

# What Are Skeletans and How Do They Form?

[4]*School of Agriculture and Environmental Sciences, Delaware Valley University, Doylestown, PA USA*

* john.galbraith@vt.edu

**ABSTRACT**

Skeletans are defined in the USDA Glossary of Terms Used in Soil Survey and Soil Classification as a specific type of ped and void surface feature consisting of clean sand or silt coatings. These features may form through removal of clay, silt, organic matter, and iron oxides from specific sites, leaving the immobile sand and silt particles behind. Although sand grains are unlikely to be translocated in soil, some silt skeletans may be formed by translocating silt particles onto ped and void surfaces. Skeletans are referred to in the 13th Ed. of the Keys to Soil Taxonomy in various ways. They are listed as clay depletions (a type of redoximorphic feature), as diagnostic criteria for seven great groups and eight subgroups where saturation and reduction are not implied, as tongues of albic material, interfingering of albic material, coatings of albic materials, or uncoated sand and silt grains in multiple places. The definitions of skeletans in the literature are variable as are the processes mentioned in their formation. The processes may include eluviation-illuviation, oxidation-reduction, gleization, lessivage, chelation, and ferrolysis. The presence of albic materials and skeletans are diagnostic criteria in both the World References Base for retic properties and albeluvic glossae in natric, argic, and fragic horizons and in US Soil Taxonomy classification systems for glossic horizons. A literature review on the formation of tongues of albic materials and skeletans will be presented.

# Abundance of Luvisols, Retisols and accompanying 'glossic' soils in NE Poland. Ecological implications

**Kabala, C.[1*], Ksepko, M.[2]**

[1] *Wroclaw University of Environmental and Life Sciences, Wroclaw, Poland*

[2] *Bureau for Forest Management and Geodesy State Enterprise, Bialystok Branch, Poland*

*E-mail: cezary.kabala@upwr.edu.pl

**ABSTRACT**

The western range of Albeluvisols on soil maps of Europe abruptly ends at the border between Poland and Belarus, as albeluvial tonguing has not been identified in Poland at any classification level (till 2011). The third edition of WRB (2014) replaced Albeluvisols with Retisols and allowed tonguing (as retic/glossic properties) in Planosols and Stagnosols, which precede Retisols (and Luvisols) in the key to References Soil Groups (RSGs) of the WRB. This change is expected to have complicated the deciphering of the transition of Albeluvisols/Retisols to Luvisols in Poland and surrounding countries. A set of 166 forest soil profiles with Bt horizons in NE Poland, just at the border with Belarus, was analysed to approximate the abundance of tonguing (retic/glossic) in the Bt horizons, to establish classification of these soils in terms of the 4th edition of WRB (2022) and to describe the relationships between RSGs and forest vegetation, the latter identified as phytosociological plant communities.

The soils were developed from glacial till and cover sands on till, thus commonly having a lithic discontinuity (sand/loam) at a depth of 30-90 cm. Only 22% soils had argic Bt horizons, not accompanied by tonguing and stagnic properties; thus, they were classified as Luvisols. The other 78% were characterised by tonguing in the upper section of Bt horizon; however, only 30% belonged to Retisols, while 12% to 36% to Retic Planosols and Retic Stagnosols. The mentioned RSGs do not form large spatial clusters, but are scattered in a mosaic pattern, typically for the transition zone.

Among the identified plant communities, Tilio-Carpinetum (T-C) caricetosum remotae and T-C circetum alpinae occurred nearly exclusively on Planosols and Stagnosols; whereas, T-C typicum and T-C stachyetosum dominated on Retisols followed by Luvisols, while T-C melittetosum and T-C calamagrostietosum – on Luvisols followed by Retisols.

Data from NE Poland showed that the priority given to stagnic over retic properties, and the respective splitting of Albeluvisols among Planosols, Stagnosols, and Retisols as in WRB 2014 and 2022, better reflects the ecological relationships than merging all soils with albeluvial tonguing into one RSG, as it was in WRB 1998 and 2006. Furthermore, forest vegetation does not differ significantly on Retisols and Luvisols, indicating a small impact of tonguing on the ecological status of well-drained soils.

**ABSTRACT**

In the Smolensk Lakelike National Park (NW Russia), due to plowing, the upper horizons of sandy soils (Albic Podzols and Albic Arenosols) are homogenized, and the remaining brown layer underling the Ap horizon is barely distinguishable—this is the lower part of the spodic horizon or parent material with a specific color (fig. 1). The situation is complicated by the fact that some local lacustrine sediments are very similar in color to the spodic horizon of Podzols. During field observation, how can determine whether this is the remnants of a soil horizon or parent material? Which laboratory tests can help to separate B and C horizons in this case?

Another diagnostic challenge is the presence of bands in the lower part of these soils that do not resemble ortsands or pseudofibers (fig. 1B). In some similar soils, a cemented, brown sand layer occurs. How can we determine whether there are the results of soil processes or geological ones?

In the Geyzer Valley and worldwide, whenever there is the influence of steam-heated acid-sulfate waters, specific soils form. They have temperature ≥ 50 C at a depth of 50 cm, bright Munsell color in moist state (hue ≥ 5R, value ≥ 3, chroma 6 –8), loamy texture or finer, mineral composition dominated by kaolinite, a fluidal micro texture in reflected light (Munsell color; hue ≥ 5R, value 2.5–4, chroma 4–8). Это всё еще почва? Или геологическое образование? Если почва, то следует для нее вводить специфические критерии?

## ABSTRACT

The Kobresia pastures on the Qinghai-Tibetan Plateau (QTP) are a key feature of the world's largest alpine ecosystem (1). They occupy approximately 450,000 km2, nearly 1/5 of the area of the QTP, and dominate the headwaters of most of Asia's great rivers. Kobresia plants are typically only a few centimeters tall and form a fairly firm turf blanketing all relief positions wherever the environment allows (2, 3). The Kobresia roots are interwoven with the surface soil. This characteristic layer is called a "mattic epipedon—a mat-like surface soil layer," according to Chinese soil taxonomy. This definition is not found in other soil classification systems, but has been adopted in China primarily as a diagnostic feature for alpine meadow soils.

The occurrence of the mattic layer is fundamental to the life system there. The humble primary production feeds all animals, wild and domesticated, which in turn sustain human life and the biodiversity of the vast, yet so far pristine, land. Without this thin skin, the ecosystem is doomed to collapse. While substantial advances have been made in elucidating the vegetational and ecological underpinnings, eco-hydrological functions, and degradation processes with associated ecological risks of these life-sustaining turfs, their formation mechanism remains unresolved.

In this work, we sampled 74 turf mat profiles across Kobresia-dominated landscapes, and integrated data from 42 published sites. We analyzed grain-size distributions to trace sediment provenance and employed luminescence dating to determine the onset of turf layer development. By relating spatiotemporal pattern of turf evolution to regional climate dynamics and quantitative grazing intensity, we assessed turf mat resilience to environmental change and long-term grazing. Our findings provide unprecedented insights into formation mechanisms, spatiotemporal evolution, and resilience of this crucial, unique and prevalent system.

crossed, an irreversible shift to barren conditions can occur abruptly.

**ABSTRACT**

According to the WRB concept, Umbrisols are characterized by the presence of deep, dark and organic-matter rich Umbric topsoil diagnostic horizons, the acidic counterpart of soils with Mollic horizons such as Phaeozems, Chernozems and Kastanozems. Their high C stocks make them particularly important for C sequestration in terrestrial environments. They mostly develop in humid mountain areas, both temperate and tropical , usually on silicatic or volcanic bedrocks, and only rarely on limestone or dolostone. However, their known distribution is underestimated, as older classification systems referred to them in different ways, often associating them with soil types corresponding to Cambisols, Luvisols or Regosols. For example, Umbrisol distribution maps at the global and European scales do not show their extensive presence in the southern European Alps, where they are the most common soil type on south-facing slopes on silicatic bedrocks and sometimes even on limestone or dolostone.

Despite their similarities to non-acidic Phaeozems, the genesis of Umbrisols is very different, as is the vegetation under which they are often found. In fact, soils with Mollic horizons are usually associated wih grasslands, with which they are genetically linked, whereas soils with Umbric horizons are often found under broadleaf forests.

Also today, however, many different views exist regarding their genesis and classification. Many soils usually classified as Umbrisols have andic or protoandic properties, and they have been sometimes classified by different soil scientists also as Andisols (e.g. in NW Spain). In other cases (Southern Switzerland and NW Spain), the increasing root density and the darker colour of subsurface horizons compared to the uppermost Ah has been interpreted as evidence of podzolization, and these soils have been termed "cryptopodzols" . The widespread black lower part of the Umbric horizon has also been interpreted as a buried Ah (e.g. NW Spain). The presence of charcoal fragments derived from anthropic forest clearing has also been often observed and considered as one of the main factors controlling the stable organic matter and the dark colour. Large quantities of amorphous Fe and Al oxyhydroxides, however, characterize Umbrisols, and they usually grade into Podzols at higher elevations or on colder northward slopes. In many cases, the deep black section of the Umbric horizon below the roots does not show visible biological activity (coarse blocky subangular aggregation, very scarce pellets and monomorphic organic matter in thin section). These properties and the gradual lower boundary, which often seems to follow water percolation pathways, could be related to illuviation of organic acids, although definitive evidence is still lacking.

# Environmental factors influencing soil particle size distribution and their spatial distribution characteristics in the Tarim River Basin

**Yang Hu[1], Lei Zhou[2] , Hongjie Ji[1], Huaiyu Long[1*], Chaozi Liao[1], Aiguo Xu[1], Mengze Xu[1]**

E-mail:longhuaiyu@caas.cn

**ABSTRACT**

Soil particle size fractions directly influence soil texture, fertility, ecological functions, and agricultural production potential. This study, based on 383 soil layers from 107 typical soil profiles (0~100 cm) in the Tarim River Basin, analyzed the effects of environmental factors using non-parametric tests, correlation analysis, and random forest algorithms, and predicted their spatial distribution. The results indicate that: (1) The soil particle size fractions in the basin are dominated by sand and silt, with the proportions of sand, silt, and clay being 44.21 ± 25.12%, 45.26 ± 20.37%, and 10.51 ± 9.60%, respectively. Sand exhibits a highly significant negative correlation with both silt and clay, while silt and clay show a highly significant positive correlation. The soil formation process in the Tarim River Basin is weak, with relatively strong physical weathering and relatively weak chemical weathering. (2) Environmental variables such as geomorphology, soil type, sunshine duration, accumulated temperature, elevation, and evaporation significantly influence the spatial distribution of soil particle size fractions in the basin. Among these, geomorphology has the greatest impact, exceeding 20% across all soil layers, followed by soil type, which exceeds 10% in all layers. (3) In terms of vertical profile distribution, the proportion of sand in the 0~25 cm and 25~50 cm layers is relatively highest in the desert area, while it decreases in the 50~75 cm and 75~100 cm layers. The West Kunlun Mountains exhibit a high proportion of sand across all layers. The proportions of silt and clay in the 0~25 cm and 25~50 cm layers in the desert area are lower than those in the surrounding piedmont belt, while the opposite is observed in the 50~75 cm and 75~100 cm layers. (4) On a macro scale, the spatial distribution characteristics of soil particle size fractions in the basin are fundamentally controlled by the annular geomorphological pattern of "two mountains flanking a basin." This geomorphological pattern influences the spatial distribution of environmental factors such as soil parent material, soil type, and climate, thereby affecting the spatial distribution of particle size fractions. The findings of this study provide a basis for the precise management of soil resources in the basin and contribute to ensuring the sustainable development of oasis agriculture and ecological environment construction.

**ABSTRACT**

Soils constitute a central component of the Earth's Critical Zone, and agricultural land is a strategic resource essential for ensuring national food security, maintaining ecological stability, and supporting rural revitalization. In the context of rising global food security challenges and increasing land-use constraints, scientifically assessing soil agricultural suitability is vital for shaping agricultural production patterns that align with natural geographical structures and agricultural production laws. Responding to the national food security strategy, this study develops a systematic, standardized, and scalable framework for soil agricultural suitability assessment based on the ongoing Third National Soil Survey of China. The framework is applied at the national scale and validated through full-process practice in representative pilot counties.

The study establishes a technical specification system encompassing an evaluation index system, classification standards, and mapping procedures, and clarifies the hierarchical evaluation logic and deliverables from county to municipal and provincial levels. National-scale results show that climate- and landform-driven macro-geographical patterns largely determine the spatial boundaries and suitability grades of different agricultural land types. Significant regional differences are observed in the optimization potential and structural adjustment of cropland, forestland, and grassland, while the availability of effective reserve arable land remains limited, underscoring the need for refined spatial planning and strict protection. Validation in typical pilot counties demonstrates that the proposed framework is scientifically robust, operationally feasible, and capable of transforming soil survey data into practical decision-support products for cropland optimization and agricultural spatial restructuring. This provides a clear and implementable technical pathway for local agricultural land-use planning.

Overall, the research presents a comprehensive and scalable full-process solution for soil agricultural suitability assessment. It highlights the foundational and strategic value of nationwide soil survey data in supporting macro-level policy decisions, safeguarding agricultural productivity, and advancing sustainable agricultural development. The framework also offers a Referencesable model for countries or regions with large-scale agricultural production needs, providing scientifically grounded and practical pathways to alleviate human–land conflicts and enhance the efficiency of land resource allocation.

**ABSTRACT**

Over 25 years, research groups worldwide have been actively involved in soil spectroscopy, measuring soil reflectance across the VIS–NIR–SWIR (0.4–2.5 µm) region, primarily for chemometric applications. This effort has led to the development of numerous soil spectral libraries (SSLs), ranging from local to continental scales, each employing different sensors and measurement protocols. Because soil is a dynamic and complex system influenced by a wide array of variables, even small changes can result in significant variations in its VIS–NIR–SWIR reflectance. Consequently, accurate soil reflectance measurements are critical, as they are highly sensitive to factors such as measurement geometry, illumination conditions, sensor characteristics, and sample preparation. As a result, merging or comparing SSLs measured under different conditions (e.g., sensors and environments) remains a major challenge. With the emergence of hyperspectral remote sensing (HSR) technologies—both airborne and spaceborne—SSLs are becoming increasingly valuable for direct implementation in HSR data analysis. For such applications to be effective, harmonized SSLs at the global scale are essential. To address this need, a group of soil spectroscopy and HSR scientists began collaborating in 2020 under the IEEE Standards Association Working Group P4005, focused on Standards and Protocols for Soil Spectroscopy. This effort is aligned with the GLOSOLAN-SPEC working group, which aims to develop a globally representative, harmonized soil spectral calibration library based on VNIR–SWIR–MIR spectra and corresponding soil property References data generated by a gold-standard References laboratory. The project examines how different protocols, sensors, and measurement methods can be harmonized to achieve global consistency among SSLs. This initiative is ongoing, and the P4005 Working Group has already released draft version #17 for both laboratory and field VNIR–SWIR measurements. The protocol is currently being finalized through comprehensive discussion sessions prior to approval by the IEEE NesCom Committee, which is expected to release the standard by the end of 2026. In this paper, we describe the benefits of the protocol's harmonization capabilities, introduce standardized procedures for measuring soil reflectance, and link the protocol to field spectral measurements.

**Importance of the project**

As many SSLs are now rapidly expanding (e.g., in China, where the goal is to sample over one million soils for the national SSL), it is essential that SSL developers adopt a common protocol to ensure a shared parameterization framework. This is particularly important because SSLs underpin a wide range of applications, including precision agriculture, from ground-based measurements to airborne and spaceborne observations.

# Building a National Soil Spectral Library from China's Third Soil Survey

**Changkun Wang[1*], Xianzhang Pan[1], and Yuguo Zhao[1]**

[1] *Institute of Soil Science, Chinese Academy of Sciences, Nanjing, China*

*ckwang@issas.ac.cn

**ABSTRACT**

The Third Soil Survey of China (TSSC) has collected and preserved millions of soil samples under a consistent, high-quality protocol. This invaluable archive presents an unprecedented opportunity to construct a massive national soil spectral library. We are utilizing this resource to explore the diagnostic potential of soil spectroscopy for assessing soil conditions, determining soil classification, and predicting key soil properties, leveraging recent advances in artificial intelligence. Our systematic approach involves measuring three complementary spectral domains for each sample: visible and near-infrared (vis-NIR), mid-infrared (MIR), and X-ray fluorescence (XRF) spectroscopy. The integrated spectral data will serve as the foundation for a deep neural network model designed to be scalable for applications at various spatial levels. This initiative is critical to meeting the growing demands of precision agriculture, digital soil mapping, and soil remote sensing. Ultimately, this research aims to establish soil spectroscopy as a reliable and efficient alternative to conventional soil chemical analysis.

# The National Soil Archive of China

**Yuguo Zhao*, Zhiying Guo**

[1] *Institute of soil science, Chinese Academy of Sciences, Nanjing, China)*

*ygzhao@issas.ac.cn

**ABSTRACT**

Soil samples preserved for the long term represent a crucial component of national sci-tech infrastructure and hold significant value for research on long-term soil and environmental changes, as well as for open sharing of scientific data. In recent years, with the continuous increase in China's investment in agricultural and ecological environmental science and technology, the intensity of soil surveys has gradually expanded, and the accumulation rate of soil samples has noticeably accelerated. Consequently, there is an urgent need for relevant standards and guidelines to direct the long-term preservation of soil samples. The Third National Soil Survey serves as a "comprehensive physical examination" of China's soils, carrying epoch-making significance for both national condition surveys and scientific research. Establishing the Third National Soil Survey sample repository presents an excellent opportunity to create representative spatiotemporal snapshots of China's soils in the new era and systematically address the historical shortage of soil samples in the country. The implementation plan for the Third National Soil Survey clearly states that the sample repository is one of the primary outcomes of the survey, requiring the establishment of standardized and intelligent national and provincial soil sample repositories, along with typical soil profile specimen banks.

# Soil Type Prediction Based on Soil Formation Factors and Random Forest

**Yao Lu[1], Hui Li[1], Huan Yang[1*]**

[1]*School of Geography and Information Engineering, China University of Geosciences, Wuhan, China*

*yhsailing@163.com

This study focused on Huaping Town, Jianshi County, Hubei Province, China. A soil type prediction model was constructed by utilizing soil-forming environmental factors — including Climate (long-term monthly averages of precipitation, temperature, and potential evapotranspiration), Organisms (monthly Normalized Difference Vegetation Index), Topography (such as DEM, slope, valley depth), Parent Material, and Human Activities (land use) — in combination with Latin Hypercube Sampling and Random Forest algorithms. The model identified 31 soil types within the study area, achieving an overall prediction accuracy of 81.79% and the Kappa coefficient of 0.8. This demonstrated the method's effectiveness in supporting precise regional soil resource surveys and digital soil mapping, providing a reliable foundation for extending this approach to the entire county to generate a complete soil type classification result. The importance analysis of environmental factors further revealed the dominant mechanisms governing soil development and differentiation. Specifically, temperature and hydrological conditions served as the fundamental control, with moisture conditions in summer and autumn exerting a particularly significant influence. Topographic factors played dual roles in directly describing landforms and indirectly regulating the spatial distribution of temperature and hydrological conditions. Parent material types and human activities drove the local differentiation of specific soil types. Through both model predictions and mechanism analysis, this study validated the reliability and interpretability of the digital soil mapping method for identifying soil types in mountainous areas. The findings provide a scientific basis for refined soil resource management and land quality assessment.

# Construction of Hainan Soil Spectral Library Driven by Large Model and Mapping of Organic Matter at 30m Resolution

**ABSTRACT**

Tropical regions have high temperatures and heavy rainfall, complex soil formation conditions, and highly heterogeneous soil physical and chemical properties and spectral responses. It is urgent to rely on large-scale measured sample points to construct a standardized soil spectral library and form high-resolution soil organic matter spatial distribution products to provide support for farmland management and soil quality assessment. This study is based on approximately 6000 soil samples and supporting physical and chemical data collected in Hainan Province, and constructs a tropical typical soil spectral database. A 30 meter resolution soil organic matter mapping framework driven by a large model is proposed.

In terms of database construction, in response to the characteristics of high dimensionality, large volume, and frequent updates of spectral data, the VIS-NIR spectra of soil samples and 18 physical and chemical indicators are encoded and stored under a unified primary key. Introduce column based storage and wavelength band indexing for spectral curves to achieve fast retrieval based on wavelength ranges, soil types, and other conditions. Build automated quality control and storage algorithms, complete spectral anomaly detection, spectral segment cutting, and batch naming, and record operation logs through triggers to ensure data version and operation traceability. Compared with traditional table based spectral data management methods, this spectral library exhibits higher stability in terms of data consistency and ease of use.

In terms of mapping methods, this study first used texture grouping as a clue to construct a sub model for texture spectral inversion, providing high-quality response variables for subsequent regional mapping. Subsequently, multiple covariates such as terrain, climate, vegetation index, land use, and parent material were selected, and textual data on soil formation environment and cultivation system in Hainan and surrounding areas were collected to fine tune the general large-scale model in different domains. The adaptive recommendation of partition covariates and model structure is completed by the large model, and the prediction is completed. Then, residual kriging is used to correct the error.

The results indicate that the Hainan Soil Spectral Database can significantly improve the robustness and portability of soil organic matter inversion. Compared with traditional mapping methods, the mapping method driven by large models achieves higher accuracy and more reasonable spatial distribution patterns in verifying sample points, especially in terrain transition areas and sparse sample areas where the advantages are more obvious. The final generated 30m resolution soil organic matter distribution map of Hainan Province can finely depict the differences between major agricultural land types, providing a new data foundation and methodological paradigm for farmland management in tropical regions.

**ABSTRACT**

Survey-based soil spectral libraries provide a critical foundation for large-scale soil property estimation and agricultural management. However, their application is often constrained by variations in soil physicochemical conditions, among which soil pH represents a key but underexplored source of spectral heterogeneity. Soil pH regulates the chemical environment of soils and controls the ionization state, aggregation behavior, and mineral association of soil organic matter (SOM), thereby influencing soil aggregate structure and spectral absorption characteristics. In this study, we investigate how pH-driven changes in SOM states affect spectral responses and the stability of SOM prediction models within a laboratory-based spectral framework. Soil samples were collected from Hainan Province, China, a tropical region characterized by strong weathering, high Fe and Al oxide contents, and a wide pH gradient from strongly acidic to alkaline conditions. Laboratory Vis–NIR spectra and soil properties were analyzed by stratifying samples into four pH classes. Preliminary results indicate that strongly acidic soils exhibit weakened SOM-related absorption features, while neutral to weakly alkaline soils show more stable and distinct spectral responses. Comparisons among non-stratified models, pH-informed models, and pH-stratified models are conducted to evaluate the influence of pH on model robustness. This study highlights the importance of pH-aware strategies in the construction and application of survey-based soil spectral libraries and provides mechanistic insights for improving their reliability in agricultural management and soil monitoring.

# A Global Transformer Framework for Aligned Soil Spectral Analysis Across Sensors and Continents

**Kritharoula Anastasia**[1*], **Tziolas Nikolaos**[1]

[1] *Southwest Florida Research and Education Center (Department of Soil, Water and Ecosystem Sciences, Institute of Food and Agricultural Sciences, University of Florida, Immokalee, USA)*

*akritharoula@ufl.edu

**ABSTRACT**

Soil spectroscopy is widely used for estimating soil properties, yet its large-scale application remains constrained by differences in sensor characteristics, spectral ranges, and resolutions. As global soil spectral collections increasingly combine data from heterogeneous instruments, there is a need for modeling frameworks that can align partially overlapping spectra without relying on sensor-specific calibration or strict wavelength standardization.

We propose a global transformer-based framework for aligned soil spectral analysis, coupled with an interoperable, web-based platform designed to support multi-sensor and multi-regional soil assessment. The framework is developed using a large and diverse soil spectral dataset comprising more than 80,000 samples, drawn primarily from open-access soil spectral databases, spanning five continents and covering visible–near infrared (VNIR) and mid-infrared (MIR) domains across multiple laboratory and field sensors.

At the methodological level, the framework adapts the Masked Autoencoder (MAE) paradigm to one-dimensional soil spectral signatures, using a self-supervised reconstruction objective to learn aligned representations from partially overlapping and incomplete spectral inputs. By reconstructing masked wavelength segments, the model accommodates variable wavelength coverage and sensor configurations without explicit spectral resampling or harmonization. Spatial context is integrated through latitude–longitude encodings based on sinusoidal positional features with learnable weights, enabling the joint modeling of spectral and geographic information.

Preliminary experiments indicate that representation-based modeling improves predictive performance relative to these baselines, with relative gains on the order of 10–20% in explained variance for key soil properties such as soil organic carbon and clay content, alongside consistent reductions in prediction error.

The learned representations and downstream predictions are made available through a global, publicly accessible web-based interface supporting multiple spectral formats and sensors. The platform is designed to provide consistent access to soil property estimates across regions lowering technical barriers for researchers, practitioners, and other stakeholders to interact with large-scale soil spectral data.

# Toward Global Soil Spectral Interoperability: Domain-Invariant Latent Embeddings with Federated Learning

## ABSTRACT

Decentralizing soil spectral libraries is becoming essential for building globally robust soil-property models, because the most valuable datasets are spread across laboratories, universities, and agencies and cannot be readily pooled. In practice, cross-institution collaboration is frequently constrained by data sovereignty, intellectual property, and internal policy, making centralized "mega-libraries" difficult to establish even when the scientific value is clear. Meanwhile, libraries remain highly heterogeneous across regions and instruments, with differences in wavelength coverage, spectral resolution, sample preparation, and preprocessing protocols. This fragmentation induces strong domain shifts that degrade model transferability and motivates calibration-transfer and harmonization efforts that can operate in decentralized settings while preserving contributors' privacy. Federated learning (FL) offers a practical mechanism for multi-institution training without centralizing raw spectra, but standard averaging-based FL (e.g., FedAvg) can be insufficient under strong cross-client heterogeneity: client updates often drift toward local "lab/instrument style," resulting in weak generalization on mixed, held-out server test sets that better reflect real-world global deployment.

We propose a representation-first federated framework that learns a shared, library-invariant latent space and then performs downstream federated regression. In Stage 1, we pretrain a conditional variational autoencoder (cVAE) to map spectra into compact latent embeddings that preserve soil-relevant variation. To explicitly suppress library/instrument signatures, we attach a domain discriminator to the encoder and apply adversarial training with a gradient-reversal layer, encouraging embeddings that are informative for soil variation but uninformative of the originating library. In Stage 2, we train federated predictors on these embeddings to estimate key soil properties and indices.

In this setting, each partner retains a local, library-specific model and full control over its spectra and preprocessing choices while simultaneously contributing to a shared global model that would otherwise be infeasible or prohibitively time- and computationally demanding to build under centralized cross-country scenarios. Early results show that embedding-based federated training can achieve performance comparable to centralized pooling of libraries, while avoiding the exchange of raw measurements and sensitive metadata. By exchanging only model updates and compact, domain-invariant embeddings, the framework supports privacy- preserving global interoperability and provides a practical pathway for sustained, multi-partner collaboration without creating a centralized "mega-library."

# A Novel Soil Type Inference Method Using AI Large Language Models

**ABSTRACT**

Based on pedogenetic theory, constructing soil-environment relationship models is a widely adopted approach for inferring soil types. While machine learning-based soil type inference models can characterize the complex nonlinear relationships between soil types and pedogenic environmental factors, they are unable to effectively integrate expert knowledge of soil genetic classification. In recent years, large language models (LLMs) represented by ChatGPT and Deepseek have developed rapidly, achieving a certain level of comprehension of pedological knowledge and thus providing a novel avenue for developing soil type prediction models that can incorporate expert knowledge of soil genetic classification. In this study, we collected soil sampling data and environmental data related to soil-forming factors. Guided by expert experience in soil genetic classification, numerical environmental variables were converted into textual knowledge, which was then encoded using LLMs to develop a soil type prediction model integrated with expert knowledge of soil genetic classification. To further enhance the overall predictive performance, ensemble learning methods were employed to fuse the inference results of machine learning-based numerical models and LLM-based knowledge models. Collectively, this study proposes a new perspective for the development of soil type inference models using AI LLMs, and may address the limitation that traditional inference methods cannot effectively integrate expert knowledge of soil genetic classification.

# The 3rd National Soil Survey of China: Integrating the Past and the Future

**ABSTRACT**

National soil survey is often a great campaign in every part of the world. Up to now, only a few countries have announced conducting soil survey in national scale. Successful experiences from countries are different.

China conducted its second soil survey program in early 1980s, which coincided the great revolution of its land ownership system and massive adoption of new agricultural technologies. It is widely recognized that the second soil survey boosted the agricultural production and contributed enormously to food security.

After 40 years of dramatical changes of land use and management, substantial soil changes have been perceived via local and case studies. However, the whole picture of soil changes through the country is still a guess. Given this background, China launched its 3rd national soil survey in 2022. This five-year (including one year pilot survey) program aims to clearly illustrate the actual soil health conditions and how soils have changed after four decades of intensive soil use.

This new survey has fully taken advantage of modern soil survey technologies. Covering preselection of sampling sites, field operation tools, instant soil measurement and sophisticated data management technology, the survey have combined classical soil survey skills with cutting-edge GIS, RS and AI technologies, realizing a fast and more accurate data acquiring and processing for soil health assessment, soil suitability analysis and all-around interpretation. It is expected that this new survey will contribute to high-quality development in the coming decades and, provide a model to those areas may expect new soil survey or monitoring plans.

*E-mail Address of Presenting Author: huanglm@igsnrr.ac.cn

**ABSTRACT**

Grassland ecosystems in arid regions are highly vulnerable to degradation due to the synergistic effects of climate change and anthropogenic disturbance, yet comprehensive evaluations of grassland soil quality (GSQ) dynamics and controlling factors are still lacking. This study assessed the spatial variability and primary drivers of GSQ across four different types of grassland (lowland meadow, LM; temperate steppe, TS; temperate desert steppe, TDS; and temperate desert, TD) along an arid east-west transect in Northwest China, using an improved soil quality index method based on minimum (GSQImds) and total (GSQItds) datasets, to inform tailored management strategies. Results demonstrated strong correlations between GSQImds and GSQItds for all grassland types ($R^2$ values: LM = 0.93, TS = 0.74, TDS = 0.86, TD = 0.81; $P < 0.01$), with regression curves closely following the 1:1 line, confirming the reliability of minimum datasets for GSQ evaluation. LM and TS exhibited significantly higher GSQImds values (0.46 ± 0.13 and 0.45 ± 0.15, respectively) than TDS and TD (0.28 ± 0.14 and 0.31 ± 0.12, respectively) ($P < 0.05$). Spatially, GSQImds decreased with increasing aridity but displayed a bimodal relationship with altitude, peaking at low (<500 m) and high (>1500 m) elevations. Fencing significantly enhanced GSQ in TS and TDS but not in TD, indicating type-specific management responses. Random forest analysis identified soil properties as the dominant GSQ driver (42% contribution), followed by vegetation (21%), terrain (19%), grazing intensity (11%), and climate (7%). Structure equation modeling further revealed direct positive effects of soil and vegetation on GSQ, negative direct impacts from grazing, and indirect influences from terrain and climate. The generally low GSQ in the arid region of Northwest China underscores the urgent need for targeted soil management strategies, such as grazing exclusion, rotational grazing and revegetation, especially in arid and overgrazed areas.

# Hydraulic Properties of Artificial Soil Constructed from Agricultural and Forestry Waste

**Yarun Wang**[1*]

[1] *Institute of Plant Nutrition, Resources and Environment, Beijing Academy of Agriculture and Forestry Sciences, Beijing 100081,China*

## ABSTRACT

The utilization of agricultural and forestry waste in creating artificial soils is a promising strategy for waste recycling and soil development. However, the impact of waste content on soil hydraulic properties remains a critical issue. This study aimed to investigate how replacing field soil with varying proportions (15%, 30%, 45%, and 60%) of mature agricultural and forestry waste (MAFR) affects the hydraulic properties of newly constructed artificial soils, thereby providing a theoretical basis for optimizing substrate formulations. We constructed layered artificial soils and compared four treatment groups (NL-1 to NL-4) against a control of pure field soil (HT). Key hydraulic parameters, including particle size distribution, saturated hydraulic conductivity (Ks), and soil water characteristic curves (SWCC), were systematically measured. Increasing the MAFR proportion generally enhanced soil structure, leading to higher saturated water content and Ks. Notably, the 45% replacement rate (NL-3) achieved the optimal balance, exhibiting the highest Ks (5.35 × 10-3 cm·s-1), which facilitates rapid drainage. While the 60% replacement (NL-4) improved porosity, its water retention curve indicated potentially weaker water holding capacity compared to other treatments. Interestingly, a critical threshold was observed at the 30% replacement rate, where the available water capacity (AWC) reached a minimum before increasing with higher MAFR additions, likely due to a shift in the soil's pore structure. The addition of MAFR significantly improves the hydraulic performance of artificial soils compared to pure field soil. The 45% replacement rate (NL-3) is recommended as the optimal formulation, achieving a superior balance between rapid water drainage and sufficient water availability, effectively addressing the poor aeration and slow water transport issues common in traditional field soils. These findings offer a practical guide for developing high-performance artificial soils from recycled organic waste.

# Investigating the Dry Color Requirement for Mollic and Umbric Horizons

*whernandez@vt.edu

**ABSTRACT**

Soil color can act as a proxy for numerous soil properties including SOM, SOC, hydrologic regime, iron and manganese content, clay content, and minerology. In addition, soil classification often relies on color data, including the classification mollic and umbric horizons. However, there is little data available which provides scientific justification for the dry color requirements separating mollic and umbric epipedons. Consequently, the proposed work aims to address these knowledge gaps by investigating dark-soil color change upon drying. Moist and dry soil color data will be collected from the grasslands and eastern temperate forests of the United States using the Konica Minolta CR-410 Chroma Meter. Preliminary results show that forest soils increase in Munsell value (lightness) by 1.43 color chips upon drying, compared to 1.23 for grassland soils ($p<.001$). Forest soils had an average dry value of 4.26, compared to 3.86 for grassland soils ($p<.001$). While significant, these differences are not functionally useful for field classification purposes.

# The definitions of field characteristics in the WRB Field Guide

**Peter Schad**[1*]

[1]*Technical University or Munich, Freising, Germany*

*peter.schad@tum.de

**ABSTRACT**

Until the publication of its fourth edition (2022), the international soil classification system World References Base for Soil Resources (WRB) had a problem: The diagnostic criteria were using field soil science terms that were not defined in WRB. Neither were they defined in the FAO Guidelines for Soil Description (2006) that were often used to provide the field data for WRB classification. This became especially obvious during the field workshops of the IUSS Working Group WRB, when participants followed different understandings of field soil science terms. After some literature research, I found out where the terms were taken from: the Soil Survey Manual of the US Department of Agriculture, 1951. They were used in the Legend of the Soil Map of the World (FAO, 1974) and since 1998 in the WRB - without having been cited. Since that, they underwent some modifications - but still without definitions.

This changed with the Field Guide (Annex 1) of the fourth edition of WRB. In this talk, I will present some important (field) soil science terms, now defined for WRB (shorted definitions in this ABSTRACT):
- litter layer: loose layer with > 90% recognizable dead plant tissues (considered as a surface feature - not as a horizon)
- soil surface: directly below the litter layer
- mineral soil surface: upper limit of the uppermost layer consisting of mineral material
- soil layer and soil horizon
- soil and rock structure types (e.g. used in the criteria for the cambic, chernic, mollic, umbric, vertic and nitic horizon)
- concentrations (concretions, nodules, filaments, masses, coatings)
- redoximorphic features and their locations
- lithogenic variegates and initial weathering (to differentiate from redoximorphic features)
- stress features versus coatings
- cementation and cementation classes (needed for the criteria of the cemented horizons like petrocalcic etc., but also for cemented oximorphic features)

WRB often refers to percentages. Now, it is always stated what 100% is (by mass or by volume, fine earth, whole soil or fine earth in combination with specific soil constituents).

Precise definitions reduce complexity and avoid misunderstandings. Soil classification helps understand and use soil - but this requires unequivocal definitions.

# Achievements and challenges for international classification of human-transformed and human-constructed soils

**Kabala, C.**

*Institute of Soil Science Plant Nutrition and Environmental Protection,*

*Wroclaw University of Environmental and Life Sciences, Poland*

*E-mail: cezary.kabala@upwr.edu.pl

**ABSTRACT**

Although soils altered by humans in terms of agricultural activities, aimed at increasing the productivity of originally infertile soils, were the first to be introduced into local and international soil classifications (as Anthrosols), today much more attention is paid to the soils of urban and industrial areas, which appeared in the FAO-WRB (World References Base for Soil Resources) classification as Technosols only in 2006. These two References Soil Groups (RSGs) are based on different concepts and different sets of diagnostic criteria, leading to different interpretations of the importance of particular human activities. A relatively small upbuilding of the topsoil layer by gradual or single addition of earthen fertilizers in order to improve soil productivity results in the recognition of the diagnostic terric or plaggic horizons, introduced to the soil name as respective principal qualifier. Whereas, deep upbuilding of the soil surface, deep soil remodelling, which destroys its natural morphological profile, or the construction of a completely new soil profile consisting of a local earthen material, situated on a new anthropogenic landform, may not be the basis for inclusion of these soils in any of the anthropogenic RSG and is marked with a lower grade supplementary qualifier, such as Relocatic, Transportic, and Escalic. New qualifiers naming variable kinds of artefacts or limiting layers in Technosols are added in subsequent editions of the WRB, while the landscape factor (landforms) seems to be underestimated in recognizing human-transformed sites and soils. In addition to the obvious development of the concept of Technosols, still many human-transformed and human-constructed soils appear to remain beyond Anthrosols and Technosols, including probably most of the soils of urbanized areas, vineyards and olive orchards, but also soils of archaeological sites. This opinion results in a fairly free interpretation of some diagnostic criteria and in a soil naming contrary to the rules of WRB classification, which is uncommon for the other ('natural') RSGs. After two decades since the introduction of Technosols to the WRB and the continuous development of this RSG, it seems necessary to comprehensively discuss and possibly revise the general concept of anthropogenic soils in the WRB, the criteria for separating between Anthrosols and Technosols, and the detailed criteria for diagnostic horizons and materials referring to human-transformed and human-constructed soils.

# Reassessment of the anthropogenic soil's classification of Slovakia - basic principles and criteria

**Jaroslava Sobocká**

*National Agricultural and Food Centre, Soil Science and Conservation Research Institute, Bratislava Slovakia*

jaroslava.sobocka@nppc.sk

**ABSTRACT**

Problem of adequate and correct description and classification of anthropogenic soils occurs very often and can result in very different approaches in many countries. To facilitate better development and refinement of classification criteria there is a need to differentiate newly defined human-transformed and human-constructed diagnostic horizons and properties. Also, confusing terminology of anthropogenic and urban soil terms and "anthropedosphere" is analysed. Ten soil classification systems over the world were overviewed in relation to applied principles and criteria of anthropogenic soils and substrates. Cultivated horizon is well-known described horizon in many scientific References, and no substantial changes are required. The real problem lies in technogenic soil types and their transient subtypes. Two groups of anthropogenic soils (cultivated and technogenic) are the subject of our reassessment in terms of soil classification principles, distinguishing criteria, and ordination into the soil References groups. The issue of re-evaluation of the current system of anthropogenic soils of the Morphogenetic Soil Classification (MSCS 2014) is observed in coincidence with anthropogenic Soil References Groups in the World References Base for Soil Resources (WRB 2022). Both observed groups are differentiated by cultivated horizon(s) (in the MSCS "in-situ" developed soil material) affected by permanent deep cultivation; and by anthropogenic horizon(s) (in the MSCS "ex-situ" developed from human transported and altered material (HTAM) as a result of technical human activities. The soil-forming substrate is a significant part of the soil mass especially for technogenic soils. Several improvements in technogenic soil diagnostics, including a new artefact percentage proposal have been proposed. Also list of anthropogenic substrata is highlighted as inevitable to consider. Some correlations with similar systems of anthropogenic soil and anthropogenic substrata were made and discussed. Recognition confirms a lack of anthropogenic substrates system in most soil classification systems. The connecting element is the References classification of WRB soils with related anthropogenic materials: artefacts, technic hard material and anthropic qualifiers. Comparing systems; several attributes were similar like presence of artifacts or human transported and altered material or human-induced properties like qualifiers Ekranic, Urbic, Spolic, or Garbic applied in Slovakia.

# Soils constructed and transformed by different cultures in the Mexico Basin: from the Teotihuacans to the Aztecs

**Ma. del Carmen Gutiérrez-Castorena[1*], Cecilia Chávez Hernández[1], Carlos A. Ortiz-Solorio[1], Javier L. Toxqui-Roldán[1], Edgar V. Gutiérrez Castorena [2]**

[1] *Programa de Edafología, Campus Montecillo, Colegio de Postgraduados, Texcoco, México.* *castor@colpos.mx

[2] *Facultad de Agronomía, Universidad Autónoma de Nuevo León, México.*

**ABSTRACT**

The earliest humans recorded in the Mexico Basin date back 30,000 years, although there is evidence that they inhabited small villages on the shores of Lake Texcoco during the Upper Pleistocene epoch, at the conclusion of the ice age. This period also saw a significant technological change, with more intensive and complex manufacturing of stone artifacts and obsidian tools. Despite the ample resources provided by the lake environment and the wooded areas, many native communities were marginalised to hilly areas or small islands in the ancient Lake Texcoco. This led to the construction of terraces and embankments for food production or building construction. The objective of the study was to characterize and classify the Anthrosols and Technosols built under different pre-Hispanic cultures in the Basin of Mexico. The geographical area under consideration is situated within the Neovolcanic Belt, in the central portion of contemporary Mexico. A comprehensive analysis was conducted on four distinct cultures: the Olmec, Teotihuacan, Aztec, and Acolhua. The main objective was the relationship between these cultures and soil construction and transformation. Subsequently, physical and chemical analyses were conducted, and the soils were classified according to the World References Base (WRB, 2022). The results of the study indicate that each culture had a different impact, depending on its needs and the environment, resulting in Technosols or Anthrosols. All pre-Hispanic cultures utilized obsidian in the fabrication of tools and weapons, the extraction of which commenced 2000 years ago. This activity resulted in a transformation of the environment, as substantial quantities of flakes and technical materials accumulated, leading to the formation of Technosols and, in some cases, Histosols-Technosols, as technical materials and organic materials (secondary vegetation) were intercalated. In the Teotihuacan area, the presence of Technosols, which contain technical materials such as volcanic tuffs or scoria, and different benches where crops were cultivated using cajetes (small holes) has been documented. The formation of Anthrosols occurred in Acolhua communities, where terraces were constructed for diverse purposes, including food production and the cultivation of medicinal and ornamental plants. An additional category of Anthrosols is represented by chinampas, a feature of Aztec culture, which are accumulations of lake sediments and organic materials, (constructed small island). This activity produced high-quality soil conducive to the cultivation of food, flowers, and vegetables, with two harvests per year. Given the diversity of activities and environments, soils can be classified very well at the References group level. Nevertheless, at the primary and secondary qualifier levels, the morphology and processes of these soils are not always reflected.

# History of the concept of Technosols, and other soils in urban areas

**Wolfgang Burghardt**[1]

[1] *Soil Technology, Faculty of Biology, University Duisburg-Essen, Essen, Germany*

*Email: wolfgang.burghardt@uni-due.de

**ABSTRACT**

The attempt to organize the research of soils in urban areas by the establishment of a Working Group Urban Soils (Arbeitskreis Stadtböden) of the German Soil Science Society by Wolfgang Burghardt in 1987 did confront soon soil scientists with the great amount of man-made, technic materials. 6 groups were distinguished: Ashes, slag, construction waste, rubbish, sewage sludge and industrial sludge, and others by the WG. Letters of Identification and Characteristics of Technic Substrates were developed for mapping, for knowledge about their functions and risk management. For designation G. Fried of the Federal Geological State Office of Bavaria made 1988 the proposal to distinguish 3 groups: Allosols - tipped natural soil material, Technosols - from technic material, and Phyrosols - from mixtures of both. The concept of Technosols was born. Blume reported from early soil mapping of the city of Berlin of clearly identifiable soil development processes (Ah-formation, browning, carbonate leaching etc.) in soils from technic materials similar as in natural soils. He showed by this that soils from technic substrates can be included in the system of classification of natural soils. Thus Technoregosols, Calcaric Technoregosols etc. were created and are content of German urban soil maps, e.g. of the city of Berlin.

The ISSS established a WG Urban Soils on the 16th WCSS in Montpellier, France, 1998. The first conference was organized in Essen, Germany by Wolfgang Burghardt and titled SUITMA-Soils of Urban, Industrial, Traffic and Mining Areas. Thus SUITMAs became the name for urban soils. By international interest urban soils became a thematic of WRB. Andreas Lehmann proposed the inclusion of Technosols in the WRB 2006. By Peter Schad and Andreas Lehman an excursion about urban soils in the heavy industry region of the Ruhr, and the cities Halle and Stuttgart, Germany was organized. The soil group Technosols with detailed description of Qualifiers was included in the WRB (2014). Technosols are defined in the WRB (2006,2014) as soils without significant or only weak soil development processes. However, urban soil investigations cited already a number of different distinct visible processes in some Technosols. There are two types: 1. Changes of the deposited technic substrates and 2. by processes induced by the urban environment. Example for 1. are slags from iron industry which are from Ca-silicates and are transformed to CaCO3. This formation to Carbonatosols happens within few decades. Concrete consist of Ca-Silicate too. It occurs frequent in urban soils. Studies are missing, 2. Dust infiltrates in gaps of pavement stones and plates (Dialeimmasols), particle intrusion occurs in diverse types of macadam (Particle Intrusols), reduction conditions by oxygen deficit underneath sealed sites (Reductosols). Beside them large areas are occupied by relict, cut, fossil, micro- and meso-climate controlled, and intense drained or leached soils.

# Extending Technosols? The status of human-transported materials in soil classification

**Marcin Świtoniak[1*], Łukasz Mendyk[2], and Maciej Markiewicz[1]**

*[1] Nicolaus Copernicus University in Toruń, Faculty of Earth Sciences and Spatial Management, Department of Soil Science and Landscape Ecology, Toruń, Poland*

*[2] Poznań University of Life Sciences, Faculty of Agronomy and Bioengineering, Department of Soil Science and Land Protection, Poznań, Poland*

*swit@umk.pl

**ABSTRACT**

Technosols are commonly recognized as the most explicitly anthropogenic soil group. However, their definition in the World References Base for Soil Resources (WRB) remains largely dependent on the presence of diagnostic technical features—particularly man-made artefacts, technogenic hard material or geomembranes. As a consequence, WRB limits Technosols to soils that contain artificial products, excluding many soils derived from human activity that involves s boil material redeposition but not fabrication.

This raises a key question for modern soil cartography: should human-transported mineral material be incorporated into the definition of Technosols, even when it does not contain artefacts? In numerous engineered landforms—road embankments, reconstructed riverbanks, mining spoil, urban terraces, and flood protection structures—humans act as the dominant geomorphic agent. The substrate is therefore anthropogenic not because it contains industrial residues, but because it was redeposited purposefully by humans. Under current WRB rules, such soils – if they do not contain well-developed humus horizons, are commonly classified as other References Soil Groups (as weakly developed Regosols), despite their clearly technogenic origin and associated land-use implications.

Some national systems already acknowledge this issue. For example, the Polish Soil Classification (6th edition, 2019) includes Aggerosols, formed from thick layers of human-redeposited mineral material that later undergo natural pedogenesis, even if artefacts are absent. This approach treats human redeposition as a soil-forming process and views anthropogenic parent material itself as a valid diagnostic factor.

This presentation examines whether human-transported substrates should be recognized as technogenic diagnostic material, thus expanding the Technosol definition. Using parallel classification of selected soil profiles, we explore the conceptual consequences of such an extension for WRB, its impact on mapping and land evaluation, and the broader question of how soil classification systems should represent human agency: through artefacts, through parent material, or through both.

# Proposals for Urbic Technosols in World References Base

**Tatiana V. Prokof'eva[1*], Maria I. Gerasimova[2]**

[1] *Faculty of Soil Science, Lomonosov Moscow State University, Moscow, Russia*

[2] *Faculty of Geography, Lomonosov Moscow State University, Moscow, Russia*

tatianaprokofieva@yandex.ru

**ABSTRACT**

New data on urban soils accumulated in this century, display their specific properties along with their high diversity owing to their occurrence all over the world. Urban soils deserve a more prominent position in WRB system and some "urbipedological" qualifiers for soils beyond the Technosols RSG. The first step might be a transfer of Urbic qualifier to urbic diagnostic horizon, as it is in the Russian system; the second – enlarging the definition, the third – introducing additional urbic qualifiers.

1. Arguments in favor of urbic horizon: emphasizing the specific nature of soils in city environment and increasing urban soils importance in the array of native soils, providing a pedogenetic ingredient in urban soils. Our perception of urban soils comprises continuous accumulation of solid-phase material different in texture and/or composition (strata), both casual and intentional, and its reworking with time in a soil with urbic horizon. Therefore, such soil is named urbistratozem – a central image of urban soils; in old cities it merges with the cultural layer. Urbic Technosols with urbic horizon may have Supplementary qualifiers Urbinovic for younger soils and Urbistratic for older ones with a discriminating boundary of 20cm.

2.The definition of Urbic qualifier (WRB,2022) comprises depth-thickness parameters, share of peculiar artefacts, human-produced waste in settlements. These criteria are applicable to any material (HAM and HTM of J. Howard), and lack pedogenetic features, inevitable in a live environment on the earth surface. Such soil properties as Corg content, pedogenic structure, infiltration rate, CEC, elevated pH values, participation of biota, etc. are recommended as criteria for urbic horizon, they are accepted in the Russian soil classification system.

3. The effect of urban environment on soils and sediments varies in intensity depending on the time elapsed, human activities, initial material, and along with urbistratozems, there are soils in settlements with a "weak" urbic horizon, hence, urbic property overlying the initial soil or technogenic material. In the former case, Urbinovic Supplementary qualifier may be added to the soil name, in the latter case – Urbithyric qualifier may be proposed as Supplementary to Regosol or Arenosol. For purposefully constructed soils, we propose Artiurbic qualifier as a Principal one for Technosols, since such soils are composed of HTM arranged in a non-natural sequence adapted to urban requirements.

We also have doubts about most of supplementary agricultural qualifiers in the Technosols RG. It seems hardly possible to find rice pads or plaggen land use system (with pigs and heatherlands) in a city or abandoned mines.

# Characterization and Classification of Soils on Sedimentary Parent Rock in Kobape, Southwestern Nigeria

**Abayomi S. Fasina[1*], Joshua O. Ogunwole[1], Bolaji M. Fakorede[1], Augustus O. A. Ilori[1] and Samuel O. Ajayi[1]**

[1] *Department of Soil Science and Land Resources Management, Federal University Oye-Ekiti, Ekiti State, Nigeria*

*abayomi.fasina@fuoye.edu.ng

**ABSTRACT**

This study investigates the characterization and classification of soils derived from sedimentary parent rock in Kobape, Southwestern Nigeria, to enhance the understanding of soil properties and their implications for land use management. The research was conducted in the sedimentary terrain of the Dahomey Basin, covering an area of 8.203 hectares, where three soil units A, B, and C were identified for soil sampling. Morphological, physical, chemical, and biological properties were assessed, with soil depth ranging from 121 to 130 cm, indicating deep soils. The pH values ranged from 4.68 to 5.57, signifying strong to moderate acidity, while electrical conductivity (EC) values varied from 0.01 to 0.58 dS/m, indicating low salinity. Base saturation was measured between 28.33% and 65.02%, revealing low to moderate fertility levels. Total iron content showed high concentrations ranging from 66.60 to 333.90 mg/kg, indicative of intense weathering typical of tropical soils. The study identified dominant sandy textures, with bulk density values ranging from 1.41 to 1.55 g/cm³, indicating moderate compaction. The soils were classified according to the USDA Soil Taxonomy as follows: soil unit A as Ultic Paleustalfs, soil unit B as Ultic Haplustalfs, and soil unit C as Typic Dystrustepts. The classification according to FAO/UNESCO identified units A and B as Haplic Clayic Lixisols, while unit C was categorized as Dystric Clayic Regosols. Given the pressures on agricultural land and the rising demand for food production, this research emphasizes the need for comprehensive soil assessments to inform sustainable agricultural practices. The findings contribute valuable insights to food security and environmental sustainability efforts in the region, advocating for the integration of soil management practices tailored to the classified soil types.

**ABSTRACT**

Globally, the classification of saline soils is mostly based on soils in arid and semi-arid regions. The WRB, one of the globally accepted soil classification systems, classifies saline soils as Solonchaks, which means soils with a high concentration of soluble salts. The conditions that must be met for a soil to be classified as Solonchaks are: first, the salic layer must begin within 50 cm of the soil surface, Second, the thionic stratum must not begin within 50 cm of the soil surface, and finally it must not be permanently submerged and not located below the tidal influence line. The salic stratum is characterized by a saturated extraction pH greater than or equal to 8.5, measured at 25 °C per year, and a saturated extraction electrical conductivity(ECe) greater than or equal to 8 dS m-1, the product of the electrical conductivity(ECe) value and the stratigraphic thickness is greater than or equal to 240, or the saturated extractive electrical conductivity(ECe) measured at 25 °C is greater than or equal to 15 dS m-1 and the product of the electrical conductivity(ECe) value and the stratigraphic thickness is greater than or equal to 450. In the U.S., the Salinity Laboratory's criteria categorizes them as saline, alkali, and saline-alkali. The analytes required for classification are electrical conductivity(ECe), pH, sodium adsorption ratio(SAR), and exchangeable sodium percentage (ESP), and they are classified according to the criteria presented in Table 1. However, saline soils in Korea are soils formed by reclamation activities rather than arid and semi-arid regions, and there is a lack of research on setting salinity criteria. Therefore, this study was conducted to classify reclaimed saline soils distributed in Korea according to the criteria of WRB and the U.S. Saltwater Research Institute, to present the problems of reclaimed soil classification, and to set appropriate criteria for Korea

**ABSTRACT**

Safeguarding the future of humanity requires caring for the health of our soils. Soil classification relies on insights into soil formation and functioning, based on the premise that this provides tools for sustainable soil management. Identifying diagnostic features, which are key to modern soil classification, is often far from straightforward. This study investigates lithic discontinuities in volcanic soils along a toposequence comprising three Andosols and three Nitisols. In Western Java, Andosols dominate at higher elevations, while Nitisols occur in mid-slope positions. Andosols form through rapid weathering of volcanic ash in the presence of organic matter, producing horizons rich in allophane, Al–humus complexes, or volcanic glass, and typically exhibit heterogeneous profiles reflecting multiple eruptions. In contrast, Nitisols represent an intermediate weathering stage involving ferralitization, with silica and base leaching leaving kaolinite and sesquioxides, combined with nitidization and intensive bioturbation that generates a well-structured topsoil.

In the WRB-2022 (IUSS Working Group WRB, 2022), identifying lithic discontinuities is crucial for evaluating whether diagnostic horizons are pedogenic. These discontinuities represent significant breaks between parent materials, often marking separate depositional events, and may occur between strata of similar or different mineralogy. Determining whether two layers are separated by such a break requires checking numerous alternative criteria, several with nested subcriteria, making their application difficult and leading to ambiguous classification and genesis interpretations.

Using hierarchical cluster analysis, we apply a modified version of the method introduced by Langohr et al. (1976), which uses particle-size distribution to identify lithic discontinuities. Our findings reveal far more frequent and clearer lithological breaks in the Andosols than in the Nitisols, despite both soils having developed from similar volcanic parent materials. This contrast is attributed to differences in age and climatic influences, with Nitisols exhibiting greater homogeneity. Morphological, chemical, and mineralogical data corroborate the identified discontinuities and support the robustness of the adapted method. Our approach offers a practical alternative to the complex WRB criteria and improves understanding of soil formation processes in tropical volcanic landscapes.

**ABSTRACT**

Worldwide, human pressure on soils has intensified due to the combined effects of agricultural expansion, urbanization—both in cities and rural settlements—and increasingly dense infrastructural networks. A key driver of this trend is rapid population growth, particularly in the Global South.

We present a comprehensive framework that systematically covers the various types of human interventions affecting soil formation, soil properties, and soil functioning, including the addition of soil material and artefacts to in-situ soils, the reshaping of soil, the removal of soil, and the use of soil material for construction purposes. Particular attention is given to human-induced alterations of diagnostic horizons.

Based on the classification of about 1,600 References soil profiles, we conclude that a wide range of direct and indirect human interventions in soils are not fully captured by the current WRB nomenclature. Drawing on our framework, we propose several new supplementary qualifiers to better characterize human-altered soils. Their applicability must be further tested and documented. However, because non-agricultural human-altered soils are under-represented in conventional soil survey databases, additional efforts will be required to incorporate data from soils described, for example, at archaeological excavation sites.

**Key words**: WRB, Anthrosols, Technosols, Anthric, Anthropedogenesis

# Research on the classification of human-altered soils in China

**ABSTRACT**

With accelerating urbanization and the global call for "Healthy Soils, Healthy Cities," the scientific classification and management of human-altered and human-transported soils have become essential for sustainable urban development. International systems such as the US Soil Taxonomy and the World References Base for soil resources provide diagnostic criteria for anthropogenic influences. As one of the countries with the longest history and most intensive degree of human activity, China possesses unique advantages but also faces severe challenges in the classification of its human-altered soils. This study reviews the historical development of human-altered soil classification in China and highlights the progress made in the Third National Soil Survey, where a new suborder for human-engineered soils was introduced to address soils derived from engineering activities. To evaluate the practical applicability of the new classification scheme, this study selected 15 representative soil profiles with engineering technical characteristics from Beijing, Hebei, Henan, and Guangdong for empirical assessment. The evaluation shows that although 80% of the profiles can be properly classified into the newly added categories, key limitations remain, including inadequate categorization of polluted soils, insufficient characterization of sealed soils, and the classification of engineering fill materials was not refined enough. To address these gaps, this study propose a refined classification scheme for China's human-altered soils. It is proposed to add the Technic hardpan as an important diagnostic horizon for identifying human-altered soils. The Technic hardpan should include: Fill materials Layers, Barrier layer, and Contaminated layer. Within the Anthrosols order to accommodate soils with distinct engineering technical characteristics, a Technic Anthrosols suborder is established, comprising Transporti-Technic Anthrosols and Alteri-Technic Anthrosols groups with Contaminated, Barrier, Intrusive, and Typic subgroups. And it is recommended to add Technical Soil Family category, including Toxic, Sealed, Slow permeable, Reconstructed, Rubbish. The proposed framework enhances the scientific rigor and applicability of human-altered soil classification in China, supports urban soil health assessment and sustainable utilization, and provides a Chinese contribution to global efforts in managing anthropogenic soils.

# The rationale behind the revision of the German Soil Systematics

**Einar Eberhardt**[1*]

[1] *Dep. Groundwater and Soil, Bundesanstalt für Geowissenschaften und Rohstoffe (BGR), Hannover, Germany*

*einar.eberhardt@bgr.de

**ABSTRACT**

The roots and architecture of the current German Soil Systematics go back to the 1950ies. Taking up the ideas of Kubiena's "Soils of Europe" (Kubiena 1953), a natural system of soils was formulated that covered the pedogenetic processes which are or were active in Central Europe. The major advantages of the system's architecture were that (i) it has clear guiding soil-scientific principles, (ii) well-thought categories even on its highest hierarchical level (called divisions) covering the different water regimes, (iii) allows to incorporate not only natural, but also anthropogenic processes of soil formation, (iv) its flexibility in definig transitional soil types, and (v) last but not least its usefulness in soil survey and mapping.

After altogether eight revisions, we again and fundamentally revised the system for the new sixth edition of the German Soil Survey Guidelines that was published in 2024. First of all, soils not yet covered in the system should be included: soils (i) with advanced peat degradation with characteristics that not existed earlier, (ii) with lateral accumulation by interflow water, (iii) completely remodelled by man, and (iv) not least the Andosols and Umbrisols of WRB, which had no correlatives in the system so far. A second task was to make the system more systematic itself by removing grown inconsistencies had become part of the system, e.g. that soil characteristics resulting from similar soil forming processes were considered on different hierarchical levels in the groundwater and stagnant water affected soils classes. The marshland soils that developped by land reclamation activities along the tidal coasts of the North Sea, had a mere geographic definition rather than a definition based on a soil forming process.

The higher hierarchy of the system (division – class) had to be revised completely, to incorporate a soil-forming processes from the landscape level into a system that considered matter translocation only in vertical direction only. The former water regime-oriented definition of divisions has been extended to (now sub-)divisions of water and oxygen availability regimes. The new division level (mineral and organic soils) facilitates to identify soils with a high significance in the climate system. New classes (Andosols, Rheosols) were defined, while the epi-tidal marsh soils class has been split up and types shifted to the classes Gleye and Stagnant water soils.

As a result, the current system kept the advantages of the old system, but gained rigor and apliccability for present scientific and soil survey-related tasks. Sticking to the scientific idea behind the system – to reflect soil formation paths – instead of sticking to a tradition of formerly formulated units of the system, maintains the system's function: to have scientifically meaningful units that respond in a similar way to (environmental) processes and changes and that can, without further intermediate steps, be used in soil survey.

# Soil characterization as a tool for sustainable soil management in the Assam-Meghalaya foothill belt: Implications for humanity's shared future

**Surabhi Hota[1*] and Krishna Kumar Mourya [2]**

[1] *ICAR-Directorate of Weed Research, Jabalpur, Madhya Pradesh-482004*

*E-mail: surabhi.hota@gmail.com

**ABSTRACT**

Soil classification provides a critical framework for understanding soil behavior and guiding sustainable land use decisions essential for humanity's shared future. In densely populated and environmentally fragile regions, such as the Assam-Meghalaya foothill belt of India, fine-scale soil information is indispensable for balancing food production, ecosystem resilience, and livelihood security. This study presents a detailed pedological characterization and large-scale (1:10,000) soil classification of the Rangjuli block, Goalpara district, located at the interface of the lower Brahmaputra alluvial plain and the Meghalaya plateau.

A total of 76 soil profiles across 41 landscape ecological units were examined using field morphological descriptions, laboratory analyses of physical and chemical properties, and USDA Soil Taxonomy. Eight soil series: Ambari, Kamarpota, Kahibari, Simlitola, Madong, Sildubi, Athiabari, and Ambuk, were identified, representing Inceptisols, Alfisols, and Ultisols. Soils ranged from deep to very deep (100 to >150 cm), with textures from loam to clay, drainage classes from poorly drained floodplains to well-drained uplands, and acidic reaction (pH 4.52-5.96). Variations in organic carbon (0.53-1.98%), base saturation (18.6-94.5%), and cation exchange capacity (6.1-12.8 cmol(p+) kg-1) reflected differences in topography, parent material, drainage, and degree of weathering.

Soil classification revealed a continuum from young, hydromorphic alluvial soils suited to paddy-based systems to mature, leached upland soils better suited for plantations, agroforestry, and perennial land uses. By translating soil diversity into functional land use guidance, this study demonstrates how soil classification underpins site-specific management, reduces land degradation risks, and supports sustainable agricultural intensification-key components of a resilient and equitable future for humanity.

# Soil classification as a carrier of functional information in viticultural terroir: linking pedogenesis and wine metabolomics

**Paola Bambina**[1*]

[1] *University of Palermo, Department of Agricultural, Food and Forestry Sciences, Viale dell Scienze, Palermo (PA), Italy*

*paola.bambina@unipa.it

**ABSTRACT**

Soil classification systems, such as the World References Base for soil resources (WRB) and Soil Taxonomy, are traditionally used for soil survey, land evaluation, and data harmonisation. However, their potential to encode functionally meaningful information relevant to complex agro-ecosystems remains underexploited. In viticulture, soil is a key component of terroir, yet its influence is often assessed through site-specific physicochemical measurements rather than through integrative classificatory frameworks. This study explores whether formal soil classification systems can act as carriers of functional information capable of explaining grapevine metabolic responses and wine composition.

Eight vineyard soils from a Mediterranean wine district in southwestern Sicily were selected to represent contrasting pedogenetic pathways under controlled agronomic conditions. Each soil was morphologically described, analytically characterised, and classified according to both the WRB and Soil Taxonomy. Wines produced from grapes harvested in the immediate vicinity of each soil profile were subjected to targeted metabolomic analysis, focusing on phenolic and volatile compounds. Multivariate statistical approaches, including Principal Component Analysis and Partial Least Squares Regression, were applied to investigate relationships between soil classification descriptors and wine metabolomic profiles.

Results indicate that specific taxonomic elements, particularly those related to horizon development, texture, and secondary carbonate accumulation, explain a significant portion of metabolomic variability. After accounting for varietal effects, soils classified as Luvisols/Alfisols showed relatively homogeneous metabolic signatures, while Calcisols/Calcixerepts exhibited greater dispersion, reflecting contrasting hydrological and chemical constraints. Both classification systems captured pedogenetic attributes that align with known soil–plant interaction mechanisms, although WRB qualifiers related to horizon architecture provided a slightly more coherent latent structure in multivariate models.

These findings support the view that soil classification systems are not merely descriptive tools, but integrative frameworks that synthesise pedogenetic history into functionally relevant information. By linking taxonomic descriptors to independent biological outputs such as wine metabolomics, this work contributes to repositioning soil classification within process-based interpretations of terroir. More broadly, it highlights the potential of classification systems to support transferable, function-oriented approaches in agroecosystem assessment, bridging traditional pedology with emerging modelling and decision-support frameworks.

# Appraisal of Soil Taxonomy and the World References Base for Soil Resources Applied to Classify Purple Soils from the Eastern Sichuan Basin, China

**Qian Meng [1], Song Li [1], Bin Liu, Jin Hu, Junyan Liu, Yangyang Chen and En Ci***

*[1] College of Resources and Environment, Southwest University, Chongqing, China*

[1]13231851055@162.com

*cien777@163.com

**ABSTRACT**

Purple soil is a type of global soil that is referred to by various names in different countries,which makes it difficult to understand, utilize, and ameliorate purple soil internationally.Soil Taxonomy (ST) and the World References Base for Soil Resources (WRB) are the most widely used soil classification systems in the world.The aim of this study was to clarify the classification of purple soil in ST and the WRB and to establish a References between different classification systems of purple soil.Therefore, based on the current principles and methods of the ST and WRB systems, 18 typical purple soil profiles in the eastern Sichuan Basin were identified, retrieved, and classified.Then, the soil units of the WRB were compared with those of ST and the Chinese Soil Taxonomy (CST).The results revealed that the 18 typical purple soil profiles could be classified into three soil orders, four soil group orders, and seven soil subgroups in ST and four References soil groups (RSGs) in the WRB;each profile had its own unique principal and supplementary qualifier combinations within the soil units.It was found that when compared with the ST system, the WRB and CST systems had stronger abilities to distinguish purple soil.In addition, the WRB system was able to more comprehensively consider soil characteristics such as soil layer thickness, ferric horizon, soil color, texture mutations,and carbonate through qualifiers.However, the CST system added diagnostic characteristics, such as the lithologic characteristics of purplish sandstones and shales and the ferric properties and alic properties at the soil group and subgroup levels, which enhanced the differentiation ability of the purple soil at the subgroup level.

# Towards a simplified key and groupings of the World Resource Base for Soil Resources (WRB)

*Stephan.mantel@isric.org

**ABSTRACT**

The WRB classification system has become more of a method to describe and classify any soil encountered in the world rather that to characterize and name a spatial pattern on soil maps, while it should serve both purposes. We propose to change the governance of WRB for future deciding on changes to the system, work towards a simplified system to be used in parallel, and to better facilitate FAIR data storage of WRB in databases.

New criteria and diagnostics in the subsequent soil classification have been based mainly on field trips of the working group that looked at a limited set of soil profiles. This has led to a focus on soil profile classification rather than the mappable soil unit classification. In an effort to summarize all features of the soil profile, the qualifiers and sub-qualifiers proliferated. With this complexity, the chance of adoption by students and researchers becomes less. For database management and for standardizing and harmonizing data, the current WRB classifications are not easily accommodated because of the many qualifier combinations possible (certainly with the depth indicators added) and the change of concepts and protocols over time.

A standard protocol for the paragraph 2.3 in the WRB manual (Rules for creating map legends) has not been worked out. Nachtergaele et al. (2022), in a draft proposal to the WRB working group, proposed a simplified system for mapping WRB units. It includes to define Soil Units by a maximum 2 PQ's. For classification, soil units are further characterized by SQ's with the textural class SQ always first, followed by Skeletic - if applicable - and then all other SQ's in alphabetical order. Another simplification could be to group RSGs with similar formative processes and soil functions into broader groups (Soil Units above References Soil Groups), such as soils with high organic matter content (Chernozems-Kastanozems-Phaeozems, Umbrisols), arid soils (Solonchaks, Solonetz, Gypsisols, Calcisol, Durisols)and so forth. Evidently the grouping can and will be much debated.

A simplified system with ranked PQs will also facilitate a better backward compatibility with earlier version of the system and would also facilitate the inclusion of WRB classification for FAIR data storage of WRB in database. We propose that subgroups within WRB work on an online documentation of the WRB codelists and vocabularies (standardized, controlled lists of terms and codes used to ensure consistent data description and exchange) and a simplified system for mapping WRB units. A more user-friendly documentation would need to be developed in parallel.

# Soils of stone-wall bench terraced anthroscapes: A proposal for their classification

**Rosa M Poch[1*], and Jaume Boixadera[1,2]**

[1] *Departament de Química, Física I Ciències Ambientals I del Sòl, Universitat de Lleida, Lleida, Catalonia, Spain*

[2] *Soil Service, Generalitat de Catalunya (retired)*

*rosa.poch@udl.cat

**ABSTRACT**

Stone-wall bench terraces are widespread in Mediterranean regions, extending across both slopes and valley bottoms, creating distinct anthroscapes where hydrology, soil erosion, and development are largely shaped by the terraces themselves. Most of these terraces were (re)constructed at the end of the 19th century in the eastern Iberian Peninsula, and while they remain stable when properly maintained, land degradation occurs upon abandonement. It is essential to recognize the singularity of these man made soilscapes in order to classify and map soils accurately, contributing to the preservation of these valuable and diverse soil resources, especially amid increasing water scarcity in Mediterranean areas. In these anthropogenic landscapes, the concept of "human-transported material" is applicable. Based on this, and considering soil development along with parameters such as terrace size (height and length) and intensity (meters of stone-wall bench terraces per hectare) we propose a classification for these soils as Anthrosols (IUSS Working Group WRB, 2022), aiming to make them more relevant in soil mapping and land use planning.

# Differences in chemical properties and soil classification of Andosols under varying volcanic ash deposition in the caldera rim of Mt. Aso, Kyusyu Islands, Japan

**Haruko Saito[1]*, Kazuyuki Inubushi[2], Hiroyuki Oshima[2], Taku Kato[2]**

[1] *Graduate School ofApplied Biosciences, Tokyo University ofAgriculture, Tokyo, JAPAN*

[2] *Faculty ofApplied Biosciences, Tokyo University ofAgriculture, Tokyo, JAPAN*

* 10425001@nodai.ac.jp

**ABSTRACT**

Mt. Aso, located in Kyushu, Japan, is one of the world's largest active volcanoes. The soil in the caldera rim is Andosols. Naka-dake, the only active volcano in the central crater hills, continuously emits sandy volcanic ash that is transported eastward by the westerlies, producing thick ash deposits in the eastern rim (Miyabuchi et al., 2003). Consequently, soil formation in the eastern rim is considered younger than in other regions. In comparison, Yamaguchi et al. (2017) reported the properties of Andosols in the northern caldera rim, an area less influenced by fresh volcanic ash, and found that they have high carbon contents. However, the relationship between volcanic ash deposition and the formation process of Andosols in the Aso region has not yet been sufficiently documented.

Therefore, this study conducted soil surveys on grasslands in the eastern caldera rim and classified the soils using the Japanese Soil Classification System (Japanese Society of Pedology, 2017), WRB (IUSS, 2022), and Soil Taxonomy (USDA, 2022). This revealed the characteristics of Andosols formed under fresh volcanic ash accumulation and the properties reflected in each soil classification.

The results showed that Andosols in the eastern rim had lower soil carbon concentration, a loamy soil texture, and tended to have higher base saturation than the northern rim (Yamaguchi et al.,2017). According to the Japanese Soil Classification System, both sites were classified as "Cumulic Allophanic Andosols." In the WRB, Site 1 in the north was classified was "Hydric Silandic Andosols (Acroxic, Hyperhumic)," Site 2 was "Hypereutric Hydric Silandic Andosols (Hyperhumic)," and the eastern site was "Oligoeutric Silandic Andosols (Loamic, Profundhumic)," reflecting differences in base saturation, water-holding capacity, and soil carbon concentration. In Soil Taxonomy, Site 1 was "Acrudoxic Hydric Melanudands," Site 2 was "Hydric Pachic Melanudands," and the eastern site was "Typic Hapludands," reflecting differences in organic matter quality and resulting in different Great Group classification. Thus, even within the Aso caldera rim, the characteristics of the Andosols differ due to volcanic ash deposition. While both the WRB and Soil Taxonomy capture these differences, the properties they reflect differ. It is considered necessary to use them appropriately depending on the classification objective.

# AI Multiagent Systems as Partners in Discovery and Knowledge Synthesis for Soil Science Research

**Budiman Minasny**[1], **Alex. B. McBratney**[1]

[1] *School of Life and Environmental Sciences, The University of Sydney, Sydney, Australia*

*budiman.minasny@sydney.edu.au

**ABSTRACT**

Soil science is entering a new phase with the emergence of artificial intelligence (AI) multiagent systems. Here, we explore the potential of AI multiagent systems as a framework to support hypothesis generation, experimental design, and conceptual synthesis in soil science.

We illustrate this approach using the case of soil carbon saturation, focusing particularly on mineral-associated organic carbon (MAOC). The saturation concept posits that mineral surfaces provide finite reactive surfaces for stabilizing organic matter, implying an upper bound to long-term carbon storage. However, recent empirical evidence shows contrasting patterns: some studies report near-linear increases in MAOC even under high carbon inputs, while others emphasize methodological artefacts and the need to distinguish practical (effective) saturation from theoretical mineral capacity. This ongoing debate makes carbon saturation an ideal test case for structured hypothesis generation assisted by AI. We tasked a general-purpose multiagent AI system, to generate scientific hypotheses and experimental designs addressing key uncertainties surrounding MAOC saturation. The AI agent operates through three collaborative agents—Planner, Executor, and Verifier—that collectively search literature, synthesize knowledge, generate hypotheses, simulate critique, and evaluate alternative perspectives. The resulting hypothesis set encompassed five thematic areas: (1) effective versus theoretical saturation thresholds; (2) microbial and molecular controls on MAOC formation; (3) climate-sensitive vulnerability and persistence of MAOC; (4) cross-disciplinary mechanisms such as adsorption, aggregation, and co-precipitation; and (5) management strategies aligned to saturation state. The simulated peer review process judged the hypotheses to be conceptually coherent, diverse, and largely aligned with contemporary soil carbon frameworks.

We argue that AI multiagent systems, guided by domain experts, can accelerate early-stage discovery, support interdisciplinary integration, and formalize the often tacit reasoning involved in scientific framing. However, this should be understood as augmentative, not substitutive: challenges remain in ensuring data quality, maintaining transparency and interpretability, preventing epistemic over-trust, and safeguarding the foundational role of human scientific judgment. Multiagent AI systems have the potential to become powerful partners in designing and testing soil science knowledge, particularly as we confront global challenges requiring rapid yet rigorous scientific innovation.

# Climate and Land Use Independent Modelling of Soil Carbon Stocks

**Yuting Dai[1*], Anthony G. O'Donnell[2], and Jinshui Wu[1]**

*[1] Changsha Research Station for Agricultural & Environmental Monitoring, Institute of Subtropical Agriculture, Chinese Academy of Sciences, Changsha 410125, China*

*Email: dyt@isa.ac.cn

**ABSTRACT**

As the largest store of terrestrial organic carbon, soils play a critical role in maintaining the essential ecosystem services needed to sustain life on Earth. However, accurate estimates of global and regional carbon stocks at depth, where most of the sequestered soil carbon is stored, are difficult to determine because of soil heterogeneity and variation in the physicochemical environment over relatively short scales. As such, many modeling approaches rely on measured soil properties to estimate carbon stocks down the profile. Such parameters are not easily measured at depth and a new approach, one that can be universally applied across all soils systems, is required. Here, we present a simple, unified, mathematical model for estimating subsoil carbon using huge routinely measured topsoil (0-20 cm depth) data and two key developed parameters. Model validation was done using 22,579 soil profiles representing 11 climate zones, and 7 land use types across 149 countries and shown to be accurate and highly significant. We estimated that the global SOC stocks at 1746 and 2177 Pg in 0-1 m and 0-2 m depth, respectively. It also suggested that current models may be underestimating total soil carbon at depths to 2 metres. Our model provides robust and universal method for boosting the accuracy of global SOC projections.

## ABSTRACT

Soil respiration constitutes one of the largest carbon fluxes from land to the atmosphere and can reinforce or attenuate climate change throughout the 21st century. Nevertheless, global projections of total soil respiration (Rs) and heterotrophic respiration (Rh) still show high uncertainty, partly because global scale models tend to prioritize climate and vegetation covariates, with limited representation of pedological modulators, and because validation strategies that allow spatial and temporal leakage may overestimate generalization capacity. In this study, we evaluated the influence of soil texture on future global projections of Rs and Rh up to 2100 under SSP1-2.6, SSP3-7.0, and SSP5-8.5, quantifying the effect of including versus excluding textural variables on the estimates and associated uncertainty. We compiled annual field measurements from SRDB V5 for Rs (n = 3,288) and Rh (n = 832) and fitted machine learning models (Quantile Random Forest) to estimate fluxes and uncertainty using climatic predictors (CHELSA v2.1), net primary productivity, and pedological covariates, including soil texture and soil organic carbon from SoilGrids 2.0 and clay mineral maps. We applied repeated spatially conditioned cross validation so that observations with identical coordinates remained in the same fold, preventing artificially high performance due to temporal replicates at the same site. This strategy reduced apparent overfitting, lowering mean test $R^2$ from about 0.65 to 0.28 for Rs and from about 0.61 to 0.18 for Rh. The final model estimated present day global fluxes of 91.9 Pg C $yr^{-1}$ for Rs and 58.0 Pg C $yr^{-1}$ for Rh. For 2071–2100, projections under SSP1-2.6, SSP3-7.0, and SSP5-8.5, combined with five CMIP6 models, indicated stronger increases in Rs and Rh at high northern latitudes and smaller changes, or slight declines, in humid tropics. In the tundra, Rh increased more than Rs, which raised the Rh to Rs ratio and indicated a greater propensity for a positive soil carbon–climate feedback where warming is strongest. The inclusion of texture variables, especially clay content and the ratio of soil organic carbon to sand as a proxy for vulnerability to mineralization, reduced projected Rh and decreased inter model spread compared with configurations that excluded texture and relied primarily on climate. These results support that, even under generalized temperature increases across scenarios, soil texture and the associated mineral protection impose pedological controls that modulate the sensitivity of Rs and Rh to warming, indicating that temperature driven projections may overestimate fluxes and the magnitude of the soil carbon–climate feedback in certain environments. Projected uncertainty remained high in regions with low observation density, reinforcing the need to expand Rs and Rh measurements, especially at high latitudes.

# Use of Geophysical Methods for Mapping Eucalyptus Root Systems in Different Soil Types

**Maria Clara de Alencar Arantes Victer[1], Emerson Rodrigo Almeida[2], Ana Clara Duarte Metri[1], Gabriel Luan de Freitas[1], Marcio Rocha Francelino[1*]**

[1] *Universidade Federal de Viçosa (Soil Department, Viçosa, Brazil)*

[2] *Universidade Federal de Uberlândia (Uberlândia, Brazil)*

*E-mail: marcio.francelino@ufv.br

**ABSTRACT**

The study of root systems is essential for understanding key ecological and physiological processes in plants, such as water and nutrient uptake, soil stabilization, and interactions with microorganisms. However, root system investigations are challenging and costly due to limited access to the subsurface. Traditional approaches are predominantly destructive, including excavation and analyses of seedlings grown in pots or observation systems such as rhizotrons, which, despite providing detailed information, compromise plant integrity and disturb the surrounding environment. Recent technological advances have enabled the application of non-destructive methods, such as ground-penetrating radar (GPR) and electrical resistivity tomography (ERT), allowing in situ characterization of root systems without physical disturbance. These techniques provide valuable insights into root architecture under natural field conditions, although their performance is strongly influenced by soil properties, particularly texture, with clay-rich soils limiting data reliability. This study aimed to map the root architecture of eucalyptus trees by integrating non-destructive geophysical data with machine learning techniques across different soil types. The research was conducted in eucalyptus plantations (Eucalyptus spp.) located at the Federal University of Viçosa campus and in a commercial plantation in Belo Oriente, Minas Gerais, Brazil. GPR surveys were performed using a SIR-3000 system with 400 MHz and 900 MHz antennas. All transects were geoReferencesd using a geodetic GPS. ERT surveys were conducted using a 4-Point-Light 10W resistivity meter in a dipole–dipole configuration, with 40 electrodes spaced at 0.5 m, reaching a maximum investigation depth of 3.8 m and applying 13 progressive investigation levels. Method validation was carried out through the careful excavation of six representative trees, whose root systems were scanned in three dimensions using terrestrial laser scanning. Data integration and analysis were performed using machine learning techniques implemented in the R environment. The results demonstrated the potential of the integrated approach for characterizing eucalyptus root systems. GPR data were more effective in detecting root structures, while ERT data were primarily associated with soil physical properties. The 400 MHz antenna showed the best performance in identifying the depth range containing the largest root volume. Higher correlations with laser scanning data were observed in medium-textured soils, highlighting the strong influence of soil class on method performance.

# Exploring the controlling factors of soil spatial heterogeneity with high-resolution environmental covariates:A case study of wildfire-affected and reclaimed artificial forests in Japan

**Takuya O. Takahashi1* and Masayuki Kawahigashi1**

[1] *Department of Geography, Tokyo Metropolitan University, Hachioji, Japan*

*takahashi-takuya2@ed.tmu.ac.jp

**ABSTRACT**

Soil spatial heterogeneity is driven by complex interactions, like pedogenic and hydrological processes, serving as a key factor in nutrient cycling and vegetation dynamics. While anthropogenic (e.g., construction) or natural (e.g., wildfire) disturbances initially disrupt these spatial patterns, subsequent pedogenic processes may gradually modify them. However, the specific environmental drivers controlling spatial dependence, particularly on the micro-scale, remain poorly understood. Traditional survey methods often fail to capture the fine-scale heterogeneity of micro-topography and vegetation structure regulating this soil spatial dependence. Terrestrial Laser Scanning (TLS) was employed to obtain the high-resolution environmental indices that may drive spatial dependence in soil physicochemical properties. This study compares two different sites: (1) artificial greenery areas, representing a soil chronosequence, and (2) a forest ecosystem recently affected by fire, representing a short-term response to the disturbance. This approach can allow us a quantitative analysis of the relationship between soil spatial structure, micro-topography, and vegetation.

The study sites are anthropogenic greenery areas constructed with subsoils of Andosols (9, 15, and 52 years old) and two forest sites with eight months post-fire, classified into high-severity and low-severity plots. Soil samples collected via grid sampling were analyzed for basic physicochemical properties (pH, electrical conductivity, total carbon (TC), and total nitrogen (TN)) and site-specific properties (e.g., pyrophosphate-extractable aluminum (Alp), iron (Fep), and carbon (Cp,) and magnetic susceptibility). High-resolution environmental covariates, specifically micro-topographic and vegetation structural indices, were calculated using 3D point cloud data, obtained by TLS. Spatial dependence was evaluated via semivariogram analysis, and correlation analysis was conducted to clarify the relationship between soil properties and the covariates.

Topsoils in anthropogenic greenery areas (0-5 cm depth) exhibited significant spatial dependence of TC and Cp, reflecting humus accumulation and A-horizon development, whereas subsoils (5-30 cm depth) showed random distributions. Regarding wildfire-affected soils, preliminary results indicate that water content in surface soils (0-2 cm depth) was correlated with elevation, with higher water content at slope bottoms. This presentation will further elucidate the spatially varying relationships between these soil physicochemical properties and high-resolution environmental indices, utilizing Geographically Weighted Regression (GWR).

# The Uncertainty of the Carbon Sequestration Potential of Arable Soils in European Russia at different scales

**ABSTRACT**

Soils are the largest terrestrial reservoir of organic carbon. For the Russian Federation, which has vast and highly varied arable land, obtaining accurate, detailed estimates of sequestration potential is particularly important, given the challenges of meeting climate commitments and developing the domestic carbon credit market. Standardised methods, such as those proposed by FAO as part of the GSOCseq project, are widely used internationally to assess carbon sequestration potential. This approach uses dynamic models (RothC) and relies on global climate databases and universal algorithms to calculate net primary production (NPP), such as the MIAMI model. Although this approach ensures that results can be compared globally, it significantly limits consideration of regional and local specifics relating to agricultural practices, levels of intensification and local soil and climate conditions.

The level of detail in the model can be increased by using national data. To this end, a methodology has been developed to calculate NPP based on national statistical data at the municipal level. Using data on crop yields and cultivated areas, the biomass of plant residues and carbon input into the soil were calculated.

A 20-year forecast of soil organic carbon stock dynamics was produced using the RothC model. The RothC model has several advantages: it is accessible; it is compatible with GIS spatial data; and it is scalable from regional to global levels. This study focused on arable soils in the European part of Russia and considered different spatial levels: global, soil and ecological zones, regions and municipalities. Examples at the scale of a field were also considered. The uncertainty was estimated using the Monte Carlo method.

When using estimates averaged over time and space, the mapping uncertainty of carbon stocks and their changes have varied from 14% to 20%. Considering actual yields and the structure of cultivated areas at a municipal level enabled us to identify significant variability in agroecosystem productivity and, consequently, soil sequestration potential. There was high spatial differentiation in the carbon sequestration rates of municipalities located close to each other within the same natural zone or district. Estimates were more uncertain when the territory's natural potential was lower and the productivity of the agroecosystem depended on the degree of territory intensification.

## ABSTRACT

Black soil thickness, as one of the core indicators in black soil research, is critical for soil organic carbon storage estimation, soil erosion, and soil health, and its spatial distribution serves as an important foundation for black soil research. Previous studies on black soil thickness mapping have mostly focused on large scales or watershed scales. In Northeast China, the rolling hill topography leads to considerable spatial variability in black soil thickness at the field scale. However, existing research has paid relatively little attention to the field scale. This study was conducted in a 13-ha agricultural field in Hailun city, Northeast China. It utilized unmanned aerial vehicle (UAV) data to acquire topographic and surface soil color information of the field. Discrete wavelet transform (DWT) was applied to decompose terrain index and soil color covariates into approximation and detail components at multiple scales (including 1 m, 2 m, 5 m, 10 m, 20 m, 30 m and 50 m). Optimal scales were selected based on the Pearson correlation coefficient with black soil thickness, with scale optimization performed separately for original variables, approximation components, and detail components. The maximum relevance and minimum redundancy (mRMR) method was used for feature selection. The 10 best features were selected, and 10 models were employed for mapping. The results show that surface soil color covariates improved the accuracy of black soil thickness mapping, $R^2$ improved from 0.16 to 0.20 in the extremely randomized trees model (ERT). Notably, the incorporation of DWT components led to substantial accuracy improvements. Among these models, the ERT model achieved the best prediction accuracy among 10 models, with RMSE of 0.16 m and $R^2$ of 0.56 in leave-one-out cross-validation. The incorporation of DWT components increased $R^2$ from 0.20 to 0.56 compared to models using only original variables. This finding highlights that microtopography exerts a stronger control on black soil thickness distribution at the field scale than at regional scales, due to its influence on localized erosion, transport, and deposition processes. The integration of DWT analysis with optimal scale selection proves effective for extracting microtopographic features relevant to field-scale black soil thickness mapping.

**ABSTRACT**

When studying soil formation, it is essential to have paleoclimate data that is both regular and detailed in terms of temporal resolution. While such data can be readily acquired from paleoclimate modeling initiatives, these model outputs do not always accurately capture climate variability and its primary drivers. Indirect paleoclimate indicators—such as those derived from pollen analysis or the measurement of annual tree rings—offer reliable information about climate variability. However, these indicators vary in their temporal resolution, and none comprehensively cover the entire timeline of soil development at a fine resolution. Specifically, fine-resolution data are available only for shorter periods, whereas longer periods typically have coarser resolution.

In this study, we aim to bridge the gap between different temporal scales by identifying the main modes of climate variability using a combination of paleoclimate indicators with differing time scales in the forest-steppe region of Central European Russia, where Chernozem soils are formed. Our novel data sources include GDGT (glycerol dialkyl glycerol tetraether) biomarkers and deuterium biomarkers extracted from peat sediments and soil profiles.

To build our analysis, we utilized time series derived from the TRACE project's paleoclimate modeling data using the CCSM model. This involved decoding and converting the data into time series for specific grid cells within our study area. Through singular spectrum analysis, we identified three main variability modes. Subsequently, we refined the modeled time series using model-data fusion techniques to yield a more realistic portrayal of each mode and generated homogenized timeseries.

The resulting time series of evapotranspiration, precipitation, and temperature at the soil boundary were then employed to define the boundary conditions for the SoilGen model, which simulates soil genesis. This integration enabled us to estimate various processes, such as weathering rates, soil formation, clay migration, and carbon accumulation, during both humid and dry climatic periods relevant to Chernozem soils. The rates of these processes are particularly important for practical applications in soil science and management.

# Podzols of the north of Western Siberia – the bridge between modern soil formation and paleocryogenesis

**M.A. Chepurnova[1*], G.V. Matyshak[1]**

[1] *Soil Science Faculty, Lomonosov Moscow State University, Moscow, Russia*

*chemaryia@gmail.com

**ABSTRACT**

Podzols are widespread intrazonal soils, formed from different parent materials in diverse regions. The variety of factors contributes to their heterogeneity in morphological and chemical properties. Paleocryogenic phenomena, widespread both globally and in Russia, have a special impact on modern soil formation, including podzolization. In the past, 95% of Russia's territory was covered by permafrost, and at present the soil cover is largely associated with paleocryogenesis.

The purpose of this research is to assess the influence of paleo- and modern cryogenesis on the podzol formation. The objects are podzols of the discontinuous permafrost zone of the north of Western Siberia (Russia, 65°18'46"N 72°52'567"E). Currently, permafrost is absent in the forest ecosystems studied, although this area froze repeatedly during the Holocene. Traces of this are now widely present at various levels. Paleocryogenesis is expressed as the paleocryogenic relief (PCR) in the landscape and as ice-wedge pseudomorphs in the soil profile. PCR is presented as polygonal alternation of hummocks and depressions, height differences of 1-3 m. The pseudomorphs, formed after ice-wedge melting, are presented at a depth more than 0,5 m and are filled with loam, hosted in sand parent material. In the relief above them depressions of the PCR are formed, repeating a paleocryogenic net. A distinctive feature of soil formation in the study region are cryoturbations of various times, forms and severity, forming a complex heterogeneous parent rock, introducing specificity into soil formation.

The dominant soils in forest ecosystems are Podzols. Soil complexes are confined to PCR: Albic Glossic Podzols are formed along a net of depressions, and Entic Podzols on hummocks, the average thickness of the E horizon respectively is 45 ± 9.2 and 4.2 ± 0.8 cm. Soils in depressions are mainly sandy, while on the hummocks the loamy texture changes to sandy at a depth of 40 cm. A distinctive feature of podzols are the thick tongues of the albic horizon, occurring most commonly in depressions and developing along pseudomorphs. The average thickness of the tongues is 51.2 ± 13.8 cm, with a maximum of 150 cm. A field filtration experiment showed that the tongues are associated with the main flows of soil solutions, redistributed under the influence of paleocryogenic phenomena.

Chemically, all soils are Podzols, with accumulation of oxalate-extractable Fe and Al in the spodic horizon, but the iron balance between the spodic horizon and the bedrock is negative. Paleocryogenic loamy pseudomorphs can serve as an additional source of Fe and Al, enhancing the podzol formation process.

Morphology of albic horizon and its distribution in northern Western Siberia is associated with paleocryogenic phenomena. Paleocryogenesis forms landscapes, patterns the soil cover, redistributes soil solution flows across the relief and within profiles, and significantly transforms the evolution and morphology of podzols.

# How Periglacial Past Affected the Evolutionary Pathways of Holocene Temperate Soils: Northern Part of the East European Loess Belt

**Vasily A. Lobkov[1*], Ilya G. Shorkunov[2], and Ekaterina V. Garankina[3]**

[1] *Department of Soil Geography and Evolution, Institute of Geography, Russian Academy of Sciences, Moscow, Russia*

[2] *Department of Soil Geography and Evolution, Institute of Geography, Russian Academy of Sciences, Moscow, Russia*

[3]*Department of Geomorphology and Paleogeography, Lomonosov Moscow State University, Moscow, Russia*

*lobkov.inbox2@gmail.com

**ABSTRACT**

Modern (i.e. Late Holocene) soils of the East European loess belt often expose relict features associated not only with their Holocene evolution, but with pre-Holocene processes. The impact of the pre-Holocene stage on formation of Luvisols and Phaeozems is still actively debated. However, evidence from stable geomorphic surfaces of the watersheds prove the continuous soil development unaffected by major denudation/accumulation events such as glacial erosion of significant loess deposition at least since the Late Glacial (12-15 ka). A consistent model of pedogenesis requires both an identification of the past (relict) profiles in the welded soil body and an evaluation of soil formation as a continuous process. To achieve this goal, we conducted studies of the upland soilscapes in the marginal zone of Moscow (MIS 6) glaciation at different scales. Applying a complex methodology including UAV and geophysical surveys we revealed the organization of polypedons. The heterogeneity of soil cover is predetermined by polygonal thermal-contraction cracking during cold stages of MIS 2. As polygonal landforms almost disappeared by the end of MIS 2, the residual polygonal geological structure of the soil-forming deposits controlled pedogenesis throughout the Late Glacial and Holocene. For example, preferential flows seem to be associated with the former troughs and nodes of polygonal nets promoting the vertical translocation of solid matter. As a result, in these positions morphological features as prismatic structure, clay and silt cutans, etc.) are usually more pronounced and profound. $^{14}C$ ages of the organic matter in clay papules along the Younger Dryas cryostructures reach 16 ka cal BP while ages of humified matter filling the cryostructures reach 13 ka cal BP. Thus, the pre-Holocene stage not only prepared the substrate for interglacial pedogenesis, but also started some of the main soil-forming processes that continue to this day.

*[2] Center for Applied Isotope Studies, University of Georgia, Athens, 30602, USA*

*E-mail pd437807@mail.ru

**ABSTRACT**

The regional-scale pyrogenic events had sharp changes of frequency and intensity in the Holocene, that proves sediments studies (Novenko et al., 2021). The studies of soil pyrogenic paleoarchives in geomorphic traps (e.g., karst holes) allows to investigate the wildfires spreading at the local scale. The findings of macrocharcoal particles (>125 μm) in these traps, laterally transported only for hundreds of meters after fires, prove this issue (Matthews J. A., Seppälä M., 2014). The objective of this study is to reveal the informational role of soils for the supplement of the Holocene pyrogenic activity paleo reconstructions by local scale data.

The studies were carried out at the South-East of Kola Peninsula ("Keiva II) and Upper-Kuloy Plain ("Pinega basin"). Totally, 143 radiocarbon dates ($^{14}$C dates) were obtained from macrocharcoal particles extracted from the soil pyrogenic archives. Graphitization and target pressing were conducted in the Radiocarbon Laboratory of the Institute of Geography RAS (Moscow, Russia) and $^{14}$C AMS measurements were done at the Center for Applied Isotope Studies of the University of Georgia (Athens, USA). Dates from the "Keiva II" and "Pinega basin" are substantially complement. The oldest $^{14}$C dates relate to the Early Holocene (≈ 10.5 ka cal BP). The first increase in the probability pyrogenic periods was detected in interval 9.8-9.6 ka cal. The second increase take place in interval 1.2-0.8 ka cal BP and until the Present time. The "Keiva II" object has the increase in the probability pyrogenic periods in the Middle Holocene (Mergelov et al., 2024).

These dates prove, that the frequencies of wildfires and the quality of pyrogenic activity records can be quasi-constant at the local scale owing to the following factors: 1) the pine taiga with lichen-moss ground cover; 2) the geomorphic traps, accumulating erosional material and 3) the drained sandy soils (Albic Podzols), compile of pyrogenic archives.

**ABSTRACT**

Paleosols (ancient soils) have many definitions, dependent upon the discipline defining them. In soil science, a paleosol may be defined as an ancient soil (often with advanced development) that A) formed under relict soil forming conditions, B) is insulated from many current surficial soil genesis processes by a more recent deposit, or C) is old enough to have either been lithified or is beneath a lithified layer. There are soils on ancient landforms that may be older than paleosols, so age alone is not a defining factor. There is no minimum age for a paleosol but it is logical that they are older than Holocene age. Paleosols are not specifically identified in Soil Taxonomy. Paleosols type A are found within the Aridisols and Oxisols orders and in six 'Oxic' and 'Torroxic' subgroups. Soils in 14 'Pale' great groups, 10 'Kandi' great groups and five 'Abruptic' subgroups are old soils but do not always fit one of the three paleosol types above. Diagnostic horizons and characteristics that take a long time to develop include petrocalcic, petrogypsic, and duripans, abrupt textural change at the top of an argillic or kandic in a moisture limited environment, and unusually thick argillic or kandic horizons with minimal (< 20%) relative cutback of clay content within 150 cm, with either albic material or redder colors required (Alfisols) or optional (Ultisols). Paleosols of type B are not typically found in floodplains, on anthropogenic landforms, or in areas of ongoing disturbance and deposition. Paleosols type B are not readily identified in Soil Taxonomy, because after the younger deposit develops diagnostic horizons throughout, the entire profile is classified. At that point the soils are largely in 14 'Pale' great groups, 10 'Kandi' great groups, or five 'Abruptic' subgroups. Paleosols type C are sometimes called 'fossil soils' and are not classified using *Soil Taxonomy* but have been identified by geologists and paleontologists. A review of the types of paleosols and the specific taxa that may identify paleosols will be presented.

# Geochemical signatures (pXRF) of polygenetic soils in the Cerrado-Caatinga transition, Piauí, Brazil

**João Victor Alves Amorim[1], Gustavo Souza Valladares[2], José João Lelis Leal de Souza[3*], Wilkins Oliveira de Barros[4], Benedito Batista Farias Filho[4], Pedro Elton Douglas Martins[2], Letícia Braz de Macêdo[2], Abraão Barbosa Lemos[2], and Rafael Albuquerque Xavier[5]**

*jjlelis@ufv.br

**ABSTRACT**

The expansion of the agricultural frontier in the Cerrado-Caatinga transition (MATOPIBA) in Brazil is advancing over pedologically complex landscapes, whose polygenetic origin is often underestimated. Understanding the superposition of pedogenetic events is crucial for sustainable management, but traditional methods (morphology, physics, and chemistry) can be inconclusive. This study aimed to use portable X-ray fluorescence (pFRX) as a high-resolution tool to decipher pedogenesis and identify parent material provenance in a representative catena in the Alto Rio Gurguéia Basin, State of Piauí, Brazil. Six soil profiles (two Fluvisols, two Gleysols, one Solonetz, and one Cambisol) were described, and samples from all horizons (fine earth fraction) were analyzed by pFRX (Bruker TRACER 5g). Elemental geochemical data (K, Ca, Ti, Fe, Zr, etc.) were integrated with morphological, physical, and chemical data to validate pedogenetic interpretations. The pFRX results provided conclusive geochemical evidence that detailed the landscape's history Variation in the Ti/Zr ratios (from 1137/2005 ppm and 55/96 ppm, respectively) indicated a lithic discontinuity in a Dystric Arenosol (Thaptoferralic, Profondic, Ochric) (FG15). According to the chemical composition, the ferralic horizon was buried by sandy materials derived from Si-richer rocks. In the Abruptic Luvisol (FG05), extremely high K contents (increasing from 1307 to 5859 ppm at depth) acted as a geochemical "fingerprint," confirming the Longá Formation pelites as the parent material and source of the high Na levels (ISNa > 47%) that enhance clay translocation. On the alluvial plain, pFRX differentiated geochemically distinct Gleysols: the Gleyc Vertisol (FG04) was rich in Fe (>20,000 ppm) and Ca (>3300 ppm), aligning with its high CEC (17.97 cmolc/dm³); whereas the Sodic Gleysol (FG09) was extremely poor in Ca (<362 ppm), demonstrating distinct pedogenetic pathways (vertic vs. sodic) within a short distance. The pFRX analysis was decisive in validating the occurrence of paleosols (2Ab horizon in a Eutric Fluvisol FG13) and in differentiating depositional layers within the Fluvisols. We conclude that pFRX geochemistry is an essential and rapid tool that, when integrated with classic pedology, enables the confident decoding of the complex history of polygenetic landscapes and is fundamental for land-use planning in this agricultural frontier.

**ABSTRACT**

The ancient city of Palenque, in the Mayan territory, was established in a strategic position between the piedmont of the Sierra de Chiapas and the alluvial plain of the Michol River, becoming a dominant city during the Classic period (250-900 AD). During its construction, landscape modifications were made on different scales and intensities. In this work, we present a combined study of natural and urban soils together with technogenic materials, and geomorphological analysis based on Lidar survey. The natural soils and Technosols (backfills) properties were determined to recover different aspects of the soil memory about the environment. The geomorphological approach revealed various landscape modifications, including terrain leveling, the construction of structures, and the diversion of rivers and streams. Due to the diversion, changes in the water and sediment supply caused the modification of the alluvial fan configuration as well as the location of the travertine outcrops. Regarding the pre-Palenque soil cover, our study demonstrates the presence of yellowish, sandy-silty soils derived from Cretaceous sandstones around the site, which is also present beneath the constructions. This soil distribution differs from that of nearby archaeological sites, where limestone produces Rendzinas and Luvisol-like soils. Finally, our study showed the use of similar materials at different construction stages in the backfills (bones, shells, limestones, stucco, ceramics, charcoal, soil, and travertine); however, there were differences in their proportions. The initial stage, dated to 200-350 AD (based on a radiocarbon date from organic matter in the buried paleosol underlying the studied building), was characterized by the primary use of soil fragments. The final stages documented a significant use of limestone and travertine.

**ABSTRACT**

Loess paleosol sequences (LPS) are archives of paleoenvironmental changes over time. Comparing different LPS enables the detection of spatial differences in paleoenvironmental conditions for the same temporal period. Here we present the Baix loess profile on the western shoulder of the Rhône Rift Valley in southeastern France at 44°42'36" N and 4°43'21" E. It shows an approximately 14 m thick LPS, which is of particular importance given the location of the Baix profile in the transition zone from the current temperate to the Mediterranean zone. We argue that the LPS exposed in the Baix profile represents a previously missing link between the comprehensively analyzed LPS of the temperate zone in the north (northern France, Alsace, Germany) and those of the Mediterranean region in the south (southern France, Catalonia, Italy, Croatia). We analyzed Baix using common paleopedological methods in combination with OSL dating. In addition, macroremains were isolated by flotation and sieving. Their examination under a binocular resulted in 79 charcoal pieces, approx. 2,100 mollusk shells, approx. 450,000 earthworm calcites, and 250 volcanic ash particles, probably from the Chaîne des Puys (French Massif Central). These proxies provided valuable additional evidence of fires and trees, and supported our paleoenvironmental interpretations.

The base of the profile is a sequence of reddish Btg horizons of an Eemian to early Würmian (MIS 5) pedocomplex. This basal part ends with an erosional unconformity, which is overlain by a layer of relocated soil material and loess, containing volcanic ash and charcoal from deciduous trees. The overlying loess (MIS 4) exhibits a sequence of Bw horizons. The upper boundary of this sequence is very diffuse, indicating that these Bw horizons must have formed synsedimentarily, during increasing loess deposition. Above, a truncated Calcic Cambisol from the Middle Würmian (MIS 3) has been preserved. Unusually large loess dolls beneath indicate that considerable amounts of carbonate have been leached from this paleosol. The Calcic Cambisol is very similar to the Middle Würmian paleosol remains in the Collias loess profile, located 87 km further south, in today's Mediterranean climate. The top of the Middle Würmian Calcic Cambisol is marked by another erosion unconformity. Above, several slightly brownish horizons follow, developed in slope-wash loess (MIS 3). The lowermost one contains volcanic ash and charcoal from Pinus and deciduous trees. The uppermost section of the profile (MIS 2) does not exhibit any paleosols. Apparently, the sedimentation rate was too high compared to the soil formation rate during this period, and there was no permafrost that would have allowed for the formation of any Reductaquic Cryosols that are commonly observed in similar stratigraphic position in the LPS of Central Europe.

**ABSTRACT**

The challenges of conducting paleoclimatic reconstructions in the Southern Cis-Urals, a steppe zone in Russia, based on the study of paleosols buried beneath burial mounds (kurgans) are in the focus of this research. Over the past 30 years, one settlement, approximately 20 kurgan cemeteries, and 90-100 kurgans representing the cultures of the Bronze Age, Early Iron Age, and Middle Ages we have studied in the region. This examines pedochronosequences' features over long (>500 years) and short (≤100 years) timescales. The properties of Chernozems and Haplic Kastanozems can shift in <100 or 100-200 years, with varied directions of changes during Holocene climatic changes. When studying both long-time and short-time pedochronosequences, the set of soil properties required for paleoclimatic reconstruction is identical and includes the degree of mesofauna activity within the soil profile, morphological and chemical indicators of the humus profile (boundary of the humus horizon and its color, organic carbon content) and salinity (content of carbonates, gypsum and the appearance of their accumulation in the profile, parameters of water extract), the content of exchangeable bases, in particular Na, the value of magnetic susceptibility, the radiocarbon age of organic carbon and carbonates, and their isotopic composition. Work in short-time pedochronoseries is carried out at the limit of the temporal response of soil properties to climatic changes, which allows us to avoid errors in determining the direction of climatic changes, as well as to conduct a chronological analysis and propose a relative (earlier-later) order of kurgan construction in the cemeteries of representatives of the same archaeological culture. For the dry steppe Cis-Urals, a climate change scheme over 7,000 years, and soil subtype dynamics are presented.

The earliest kurgans of the Yamnaya culture (6000-5300 years ago) were created in extremely arid conditions, resulting in a shift from Haplic Chernozems to Calcic Chernozems. Between 5300 and 4300 years ago, the climate became gradually wetter. The area of the Haplic Chernozems broadened and shifted to the south. The analysis of Subboreal soils, which date back to 3900-3500 years ago and are found buried under the kurgans of the Srubnaya culture, shows that between 3900 and 3800 years ago, the driest climatic conditions were dominant. After the aridization stage, a period of climate softening began, marked by a gradual increase in humidity that continued until the end of the Srubnaya culture (3600-3500 years ago); Calcic Chernozems shifted further south. Frequent climate changes marked the Subboreal and Subatlantic periods' Holocene border (2700-1600 years ago). The shift of Calcic Chernozems and Haplic Kastanozems was recorded in two timeframes: 2700-2400 years ago (north) and 2400-2200 years ago (south). Around 650-600 years ago during the Middle Ages, the climate became more humid and mild, which changed Calcic Chernozems to Haplic Chernozems. The unresolved issues are presented at the end, along with the periods lacking geoarchaeological data.

# Bronze Age kurgans as a complex paleoarchive: data from paleosoils and kurgan constructions in the steppe zone of Russia

**A. Sverchkova***

*Institute of Geography, Russian Academy of Sciences, Moscow, Russia*
*E-mail: acha3107@gmail.com

**ABSTRACT**

Geoarchaeological investigations were conducted at four key sites within the steppe region of Russia: Krasnodar region (kurgan 1 of the Beysuzhek IX cemetery and the Shumny kurgan), Stavropol region (Essentuksky 1 kurgan), and Orenburg region (kurgan 1 of the Boldyrevo IV cemetery). Geoarchaeological studies of paleosols buried under burial mounds/kurgans and the kurgan constructions (KCs) have been carried out with the aim of determining and comparing properties of paleosols and the material of KCs, conducting paleoclimatic reconstructions, as well as obtaining knowledge on the technology used for kurgans building. The kurgans of various Bronze Age cultures have been studied in the steppe area of Russia as a single system "kurgan constructions – paleosols". The research has been carried out comprehensively: the main technologies for building of a kurgan have been identified, and the properties of paleosols and materials of KCs have been compared. This approach significantly increases the reliability and validity of the conclusions obtained, since the object of study is not only buried soils, but also kurgans themselves, the material for the construction of which was collected from the surroundings of a large nearby area.

Micromorphological and physicochemical analyses indicate that the kurgans were predominantly constructed from locally sourced soils, with minimal anthropogenic admixture. For all four studied kurgans, a comparison of the technical and technological approaches used by ancient people for the building of monumental constructions of earthen architecture has been made. Both similarities and differences in the building approaches of the studied kurgans have been revealed.

Based on a combined analysis of physicochemical and morphological data from paleosols, surface soils and materials from KCs, three stages of changing climatic conditions during the Bronze Age in the steppe area of Russia have been identified. An aridization phase during the Atlantic period (AT-3), 5700–5500 years ago, across the East European Plain steppe zone. An aridization phase during the early Subboreal period (SB-1), 4300–4200 years ago, specifically in the Kuban-Azov Lowland and Trans-Kuban Plain.

A humidization phase during the late Subboreal period (SB-3), 3500–3000 years ago, documented in the Trans-Kuban Plain.

**ABSTRACT**

The buried and surface soils of the Bronze Age settlement «Zidyan-Kazmalyar» (Dagestan, Russia) were studied. The results of morphological and analytical studies revealed significant differences between the background and buried soils. The studied soil profiles exhibit a complex structure, indicating stages of development and the influence of various factors. Buried soils at various depths indicate stable environments, while the presence of redeposited material indicates stages of intensified slope processes.

The use of the soil chronosequence method allowed us to identify differences in the properties of soils formed at different times but in the same area. The surface soils were classified as *Calcic Kastanozems (Aric, Humic, Loamic)*, with a well-developed profile and contain 2.5% TOC in the upper part of the profile. Despite the age of the burial (about 5 thousand years ago according to archaeological finds), 1.5% of TOC and dark humic horizon was preserved in the Bronze Age soil, which indicates high original content of organic matter. We suggest that buried soil of the Bronze Age formed during a relatively warm and humid climate. These conditions were favorable for the development of a rich steppe soil, leading to accumulation of organic matter and the formation of a well-differentiated soil profile. Increased moisture is indirectly indicated by the clearly visible profile of the stream channel at the foot of the slope. The formation of such a well-developed profile requires a long period without catastrophic erosional events. Transition to a cooler climate with fluctuations in humidity was recorded in the spore-pollen spectra of the Dagestan swamps [Ryabogina et al., 2019].

The soil, which dates back to approximately the Mesolithic era, has a poorly developed profile with a distinct humus and carbonate horizon and also contains gypsum inclusions. The abundance of gypsum, which is not found in other soils, and the poorly developed profile indicate an extremely arid climate that existed when this soil was buried. Physico-chemical analyses of soils, as well as phytolith and spore-pollen analyses, complement the paleoecological information about this settlement.

# Acid sulphate pedogenesis of the geological past of the Earth and beyond it

**Tatiana Alekseeva[1*], Andrey Alekseev[1]**

[1] *Institute of Physicochemical and Biological Problems in Soil Science of Russian Academy of Sciences, Pushchino, Russia*

*E-mail Address: alekseeva@issp.serpuhov.su

**ABSTRACT**

The talk covers the case study of Mid-Devonian (Eifellian) paleosol developed from rhyolite tuff (Alekseeva et al., 2023; Wang et al., 2025) and three paleosols from the weathered roof of Precambrian basement. The latter is presented by ferruginous shales and quartzites. Paleosols were sampled on the territory of actively excavated quarries. All rocks contain pyrite. The multidisciplinary study covered geochemistry, bulk and clay mineralogy, micromorphology, iron-mineralogy (XRF, XRD, SEM-EDX, Moessbauer spectroscopy). Based on obtained data paleosols were attributed to analogues of modern acid sulphate soils. Such soils developed from deposits containing sulfides. The sulfuric acid – a product of sulfides oxidation, provides pH below 4 which promotes the aggressive chemical weathering. The products of sulfides oxidation are gypsum, Fe-sulfates, Fe-oxides. Due to the numerous possible sources of sulfides (as natural as anthropogenic) acid sulfate soils are azonal. In our days they cover about 1% of the Earth`s territory. Paleosols of this type are among the first appeared. The oldest sulfate containing (kieserite, barite, gypsum) paleosols are Archean – 3.2-3.7 Ga. The remote study of Mars deposits showed that their principal chemical element is sulfur. The deposits are cemented by Mg-, Ca-, Na- and Fe- sulfates and Fe-oxides. This mineral association indicates the distribution of acid sulfate soils beyond the Earth. Martian paleosols are Archean and were arid (Retallack et al., 2023). All paleosols of the given study were developed under rootless primitive vegetation. Soil development was primarily carried out via chemical weathering with a pyrite oxidation as a trigger. The paleosols at the roof of Precambrian basement did not develop the continuous soil cover. Their specific feature was the predominantly below surface (~ 15 cm deep) transformations with the negligeable transformations of the topsoil. Such characteristics puts these paleosols on a par with epilithic/endolithic systems. The paleosol on volcanic material created the cover which thickness depended on the relief of the basement. The transformation of the parent rock affected the whole thickness, but had the localized character and was not accompanied by formation of distinct soil horizons. Present data reveals the spreading of acid sulfate pedogenesis in former geological epochs. Reconstructions of paleoclimate based on geochemical data showed that being gypseous, paleosols nevertheless were developed under humid climate.

# Indicators of the paleoecological situation in the Volga region soils

**R. Reshetnikova[1*], N. Kovaleva[1]**

[1] *Soil Science Faculty, Lomonosov Moscow State University, Moscow, Russia*

*rada3025@mail.ru

**ABSTRACT**

Several soil sections with cultural layers in settlements of different parts of the Volga Valley - the Upper, Middle and Lower Volga regions - were studied to determine the most informative soil properties for paleoreconstruction of soil formation conditions. The aim of the work was to identify the most informative inertial soil properties based on an analysis of chemical and physical properties of soils.

The isotopic composition of organic carbon of soils, the granulometric composition of soils, the gross chemical composition of soils, specific magnetic susceptibility were chosen as the most informative properties.

The isotopic composition of organic carbon and the radiocarbon age (or relative age based on archaeological data) of soils showed that during the Early Holocene, the δ13C isotope ratios were lightweight (wetter conditions), the proportion of the heavy isotope C13 increased during the Middle Ages (moisture decreased), and the values became even heavier during the Little Ice Age (increased aridization), and have become lighter again for modern times (wet conditions).

The granulometric composition of soils and coefficients calculated based on it – sorting and average diameters of sandy components – have become indicators of the genesis of soils. Most of the studied soils had deluvial and proluvial genesis, indicating the activity of water flows during the formation of profiles.

The values of magnetic susceptibility and the paleoprecipitation calculated from them (for soils of the dry-steppe zone) showed maximum values in buried horizons of the Early Holocene, medieval layers, in solonetzic horizons and in surface humus horizons. This indicates increased moisture during these periods and in modern times, and the maxima in the solonetzic horizons are also the result of the solonetzic process: a silty fraction accumulates in them, to which magnetic particles are confined.

The correlation of the analyzed properties allows us to conclude that the formation of Early Holocene soils exposed in the Middle and Lower Volga regions in humid conditions. By the Boreal period of the Holocene, the climate had become drier; horizons and cultural layers of the medieval age were formed in warm and moderately dry conditions of climatic optimum; the Little Ice Age began with increased processes of climate aridization, including due to increased anthropogenic activity. By modern times, the humidification of the climate in the Volga region is increasing. As for the late Holocene soils of the Upper Volga region, their properties of the medieval climatic optimum and the Little Ice Age are manifested by a decrease in moisture.

Thus the most inertial indicators have been selected that preserve information about climatic rhythms – the isotopic composition of soil organic carbon, specific magnetic susceptibility, and granulometric composition.

# Paleosols as a key for piecing together the past climates and the intricacies of soil processes

**Andrey Alekseev[1], Tatiana Alekseeva[1]**

*[1] Institute of Physicochemical and Biological Problems in Soil Science of Russian Academy of Sciences, Pushchino, Russia*

**E-mail Address: alekseev@issp.psn.ru*

**ABSTRACT**

Paleosols are the most important paleogeographic records which reveal paleoclimate and palaeoecology. Integration of all paleopedospheres in our research region allows us to create a nearly continuous depiction of Earth's lithosphere history. The key goal of our team's research is to analyse mineralogical and biogeochemical solid-phase records of the soil matrix to extract quantitative parameters for paleoenvironments, including climate and vegetation, throughout a broad temporal period encompassing the Holocene, Pleistocene, and Paleozoic. Numerous Quaternary paleosols were discovered in steppe regions beneath ancient monuments (mounds, kurgans, earthen fortifications), spanning the middle and late Holocene. The scientific approach involved a comparative investigation of the morphological, chemical, magnetic, and mineralogical characteristics of buried paleosols of varying ages and their contemporary counterparts. The content of soil magnetite was used as a “magnetic record” of the previous environmental conditions of the steppes, which allowed quantitative reconstructions of the climate, as well as a quantitative assessment of the shift of natural boundaries during the late Holocene in the south of the East European Plain, caused by climatic variations (Alekseeva 2007, Alekseev et al. 2020). Statistical analysis of climatic dependencies of changes in magnetic susceptibility in modern steppe soils of the south of the East European Plain demonstrated, albeit with certain limitations, the possibility of estimation the precipitation and the De Martonne aridity index (IDM) of past eras (Alekseev et al. 2023). A retrospective analysis of organic matter of soil clay fractions, incorporating NMR spectroscopy and $\delta^{13}C$ data from contemporary soils and Quaternary paleosols, additionally facilitates refinements to paleoclimatic reconstructions. Climate factors over the last 5,000 years in East European part of Russia were reconstructed using connections with magnetic soil properties, clay mineral composition, and soil carbon isotopic signatures. Similar approach was employed for the examination of Pleistocene loess-soil complexes (Alekseev, Alekseeva 2024). Bulk chemical and mineralogical composition of pre-Quaternary paleosols were utilised to reconstruct paleoclimatic and paleoenvironmental conditions. The geochemical and mineralogical characteristics of biogenic transformations of sediments and paleosol formation in the European region of Russia and the Spitsbergen archipelago during the Devonian and Carboniferous periods, along with the reconstruction of terrestrial ecosystems and climate, will be presented (Alekseeva et al. 2016, Alekseeva et al. 2025, Alekseev et al. 2025, Alekseeva et al. 2026).

# Reading the Quaternary Soil Memory: Quartz Isotope Fingerprints of Aeolian Processes in the Asian Steppe

**ABSTRACT**

Aeolian dust originating from the arid and semi-arid regions of East and Central Asia is a fundamental component of the Earth's climate system, significantly influencing regional and global atmospheric processes, nutrient cycling in marine ecosystems, and the formation of extensive loess-paleosol sequences throughout the Quaternary. While traditional models have long emphasized the Gobi and Taklamakan deserts as the primary "dust factories," the role of the vast Eurasian steppe remains a critical yet underexplored piece of the paleoenvironmental puzzle. This study adopts the transdisciplinary concept of "soil as memory" to investigate the Asian steppe's potential as a major dust source, utilizing the stable oxygen isotope composition ($\delta^{18}O$) of quartz grains as a robust provenance tracer

To establish a comprehensive geochemical baseline across diverse landscapes, we analyzed surface soil samples from twenty-four strategic sites across the Asian steppe corridor—encompassing regions in Ukraine, Kazakhstan, Mongolia, Xinjiang and Inner Mongolia. Furthermore, to examine the vertical "memory" of these landscapes and their long-term sedimentary contributions, we conducted analysis of four distinctive soil pedons located in key dust-generation zones of Mongolia and Inner Mongolia. These profiles were sampled at multiple depths (including surface and three deeper horizons) to evaluate the temporal continuity and evolution of aeolian deposition within the soil record.

Analytical results demonstrate a clear isotopic partitioning based on grain size: fine-sized quartz particles exhibit significantly higher $\delta^{18}O$ values, indicating a primary origin from low-temperature sedimentary environments—the typical precursors to regional loess deposits. Conversely, coarser quartz grains are associated with lower $\delta^{18}O$ values, linking them to high-temperature igneous basement rocks. This observed spatial and stratigraphic distribution of $\delta^{18}O$ signatures highlights the complex interaction between regional lithology and aeolian processes

Our findings suggest that the Asian steppe provides a unique "memory" of dust transport dynamics, reflecting the seasonal and historical modulation of the mid-latitude westerlies and the East Asian monsoon system. By integrating these isotopic fingerprints with soil pedology, this research offers novel insights into the provenance of Asian loess-paleosol sequences and the broader evolution of Quaternary geosystems in the Northern Hemisphere.

**Key words:** Asian Steppe; Aeolian dust; Oxygen isotopes; Quartz; Dust transport.

# More than a metaphor: soil memory as methodological framework

**ABSTRACT**

Paleopedology studies fossil soils or paleosols. It is a historical science, or as previously highlighted by Ruellan (1971), the historical branch of pedology. Soil characteristics with paleoenvironmental significance that persist (inheritance or heredity) belongs to the concept of soil memory (Targulian and Goryachkin 2004). The soil memory concept consists in rethinking how information is received, transformed, and recorded in natural bodies through self-organization of unstable dynamic systems. Soil memory, as all scientific concepts, does not manifest in the tangible world; rather, it constitutes a mental construct for comprehending reality. The soil memory is composed of an empirical data set employed to elucidate the outcomes of bio-abiotic system preserved within the geological record. Just as paleontologists do not examine dinosaurs, and archaeologists do not investigate ancient societies directly, but rather focus on material remnants such as fossils and lithic artifacts. Paleopedologists typically do not directly observe actively-forming soils. In sum, paleopedology deals with partial evidence of something that existed or happened in the past. The objects of paleopedology and pedology are similar, however, present distinctions. Nonetheless, analogy, analogical reasoning, and analogical arguments based on extant soils play a key role in paleopedological studies, even in the absence of modern analogs for specific paleoenvironments, such as Archean paleosols. Analogy is defined as inferential processes to establish comparison between selected objects, or systems of objects highlighting their similarity. In analogy, the characteristics of unknown objects are seen in the light of known objects, allowing the establishment of analogical reasoning and emergence of hypotheses that need independent verification. Soil memory has two analogic aspects: (i) analogic explanation, which highlights the most relevant features when compared to other features highlighting causal relationships; (ii) argumentation to evaluate with hypotheses. The dual analogical aspects, we argue, make the soil memory. In the context of soil memory, the concept of uniformitarianism is applied to infer conditions rather than to compare objects or systems of objects. Thus, soil memory may be regarded as a framework for identifying regularities at different scales (not necessarily universal regularities due to local and historical contingencies) in the paleopedological record. The regularities may be seen as models of causal systems, based on the "redescription" and inference of past reality through similarities (both qualitative and quantitative) between objects. Soil memory provides an "experimental context" to emphasize the observed regularities. It is more than a metaphor; it is a methodological framework.

# Paleoenvironmental significance of earthworm aestivation chambers from Cretaceous paleosols ofAraripe Basin, Brazil

**ABSTRACT**

Aestivation is a key adaptation to environmental stresses, such as seasonal drought. Earthworms, which depend on cutaneous respiration and thus require a moist environment, construct aestivation chambers to avoid desiccation during dry periods. Earthworms are highly diverse and ubiquitous in modern environments , acting as significant ecosystem engineers. Nevertheless, despite their prominence in the soil community and long evolutionary history, earthworm chambers preserved in paleosols are remarkably scarce . The present work provides detailed descriptions of pelleted chambers produced by earthworms preserved in mid-Cretaceous hydromorphic paleosols of the Exu Formation, Araripe Basin, Brazil. The results show that the chambers present sub-circular to ovoid shape with diameter of 20–80 mm. The walls are multilayered, 3–9 mm thick and composed of diverse distinct layers of reddish sub-circular and flattened pellets composed of clay material tightly attached. The chamber itself is filled with sub-circular pellets like those found in the walls. In thin section, the chamber walls consist of multilayered, reddish-brown, inorganic clay linings with incorporated grains. The grains are oriented parallel to the layer and exhibit discrete discontinuities. The walls display a sharp boundary with the surrounding paleosol fabric, defined by a thick clay lining that contains subcircular microaggregates with different sizes of tightly packed clay, and oxides with coarse mineral grains. The quartz grains are oriented inside the aggregates, in some cases different aggregates are attached to each other, forming a grano -striated pattern. Therefore, the lining composed of clay and clayish pellets suggests that the producer lined the chamber with pellets, as ingestion of soil may select the fine fractions of soil. In this scenario, the producer probably encased itself in the subcircular pelleted chamber, a behavior supported by the pelleted texture of the wall. A similar process is observed in the aestivation chambers of extant earthworms, such as Acanthodrilinae sp. and Rhinodrilus alatus. These worms mix clay with mucus and gut content, to construct their chambers, and the mucus secretion contributes to retain water, keeping the worms moist during aestivation. Yet, the aestivation behavior is supported by chambers in paleosols with hydromorphic features that suggest variations in drainage conditions with periods of increased moisture, despite the overall semi-arid conditions of the Exu Formation. Therefore, these chambers indicate that during dry season with lowered water tables, these organisms were forced to construct aestivation chambers, as observed in extant earthworms.

**ABSTRACT**

The geochemical characteristics of paleosols, particularly weathering indices and elemental ratios, are widely used for quantitative paleoclimate reconstruction in deep-time records. Geochemical climofunctions, such as mean annual precipitation (MAP) estimates derived from the CIA-K and hydrolysis indices, have been especially important for reconstructing past moisture regimes by linking elemental depletions and enrichments to climatic parameters. While these methods have provided valuable paleoenvironmental insights, most widely used calibrations are based on temperate North American soils and assume that soil moisture balance is primarily controlled by precipitation. This assumption limits their applicability in tropical to subtropical regions, where high evapotranspiration strongly influences soil water balance and modifies pedogenic geochemical signals, potentially introducing systematic biases in low-latitude MAP reconstructions.

The humidity-regime model of Gulbranson et al. (2011) attempts to overcome this limitation by integrating both water influx and efflux; however, its performance in tropical paleosols remains poorly evaluated. This regional bias raises concerns regarding the global applicability of standard paleosol-based geochemical proxies. To address this issue, we assess the performance of multiple paleoclimate proxies in tropical, low-latitude Maastrichtian (Late Cretaceous) paleosols from India. We apply the Chemical Index of Alteration (CIA-K), base cation to alumina ratios (ΣBases/Al), and a humidity-regime model to reconstruct paleoclimate conditions.

A comprehensive multi-proxy framework is used to cross-validate geochemical climate estimates with independent evidence from fossil plant assemblages (micro- and macroflora), pedogenic micromorphology, and sedimentological observations. Results consistently indicate a humid subtropical climate with high rainfall and warm temperatures, supported by moisture-loving plant assemblages and evidence for intense chemical weathering. Crucially, this study provides one of the first systematic evaluations of commonly used paleosol-based geochemical proxies and the humidity-regime model in tropical, low-latitude Maastrichtian paleosols. While geochemically inferred MAP values broadly agree with paleobotanical and pedogenic indicators, we demonstrate that North American-derived calibration equations introduce predictable, systematic biases when applied to Indian paleosols.

# Distribution, characteristics, and formation mechanism of siliceous restrictive layers in the black soil region of Northeast China

**Zhong-Xiu Sun[1]*, Qiu-Bing Wang[1], Ying-Ying Jiang[2], Si-Yi Duan[1], Xiao-Miao Yu[1], and Cheng-Cheng Zhang[1]**

[1] *College of Land and Environment, Shenyang Agricultural University, Shenyang, Liaoning Province, China*

[2] *College of Life Engineering, Shenyang Institute of Technology, Shenyang, Liaoning Province, China*

*E-mail Address of Presenting Author: zhongxiusun@syau.edu.cn

**ABSTRACT**

In recent years, extensive soil surveys have discovered that a special silica-clay composite layer is widely distributed across the black soil region of Northeast China. This layer feature, provisionally termed the siliceous restrictive layer, significantly impedes plant root penetration and soil moisture movement, accelerates slope erosion, and critically threatens regional food security and agricultural sustainability. Despite its ecological importance, the spatial distribution, physicochemical characteristics, and formation mechanisms of this layer remain unclear.

This study integrates systematic field investigations with machine learning modeling to address these knowledge gaps. The 922 soil profile records and 21 environmental covariates were compiled, and a random forest algorithm (Kappa coefficient = 0.42) was used to delineate the siliceous restrictive layer's distribution across the Northeast Black Soil Region. Results showed a total distribution area of 8137 km2, concentrated in Jixi, Jilin, Tieling, and Hulunbuir cities. Key physicochemical parameters include depth (28.80–65.30 cm), thickness (51.52–92.35 cm), silica neoformation abundance (18.50–29.62%), and silica neoformation density (302.98–629.86 g/dm$^3$).

To address characteristic patterns, 30 representative soil profiles were analyzed across diverse climatic zones, topographic positions, and geological periods. Statistical analyses revealed distinct properties including low organic carbon content, moderate total nitrogen and phosphorus levels, elevated available phosphorus, high bulk density, and weakly acidic pH. Particle size distribution showed silt dominance, while geochemical signatures exhibited elevated $SiO_2$ proportions, moderate Fe/Al ratios, high silicate activity factor (Saf), and intermediate eluviation indices.

The formation mechanism was reconstructed through multidisciplinary evidence, revealing dual regulatory mechanisms: in terrace-hilly landscapes, groundwater dynamics interact with biological cycling to drive silica accumulation; in mountainous regions, biogeochemical processes dominate, characterized by plant-mediated silica enrichment and detrital recycling.

This research provides critical insights into the genesis of siliceous restrictive layers, offering robust scientific foundations for: (1) targeted soil management strategies to enhance black soil productivity, (2) refined classification criteria for Chinese Soil Taxonomy, and (3) sustainable agricultural development in vulnerable black soil ecosystems. The integrated methodology establishes a template for investigating analogous soil horizon phenomena globally.

**ABSTRACT**

Krotovinas, the infilled burrows created by small mammals through bioturbation, represent a distinct pedogenic process and provide valuable records of soil and landscape history. Traditionally, macro- and micromorphological features are analyzed to investigate the origin of burrow fills, and ages are often estimated using 14C dating. However, in some environments, morphological features can be misleading and material for 14C dating is insufficient. This study explores the potential of luminescence techniques to address these issues. We studied a Chernozem profile with typical krotovinas, forming from fluvial sediment in northeast China. Three krotovinas of different depths and colors (two black and one yellow) were sampled, along with their respective supposedly undisturbed counterparts from the surrounding soil. We conducted single-grain (SG) luminescence dating of the K-feldspar fraction and multigrain (MG) luminescence dating of both quartz and K-feldspar fractions. Significant differences in luminescence ages between samples inside and outside the krotovinas at both MG and SG levels suggest the presence of vertical bioturbation. Comparisons of SG distributions among samples indicate that the yellow krotovina at ca.70 cm was the result of upward transportation from a lower layer and was formed after the end of the Last Glacial Maximum. The two black krotovinas at ca. 80 and 160 cm are genetically linked, and probably formed in a single, rapid, simultaneous filling event occurring no earlier than 2.7 ka. This study highlights the unique role of luminescence dating in elucidating formation processes of krotovinas and the soils in which they are found.

# The basalt – laterite sequences in the Leizhou Peninsula, South China: Indicating multiple alternations between volcanic eruption and laterite formation in the tropical region since the Middle Pleistocene

**Xue-Feng Hu*, Ting-Xiao Liu, Tian-Le Cai, Da-Lin Nie**

*School of Environmental and Chemical Engineering, Shanghai University, Shanghai 200444, China*

E-mail Address: xfhu@shu.edu.cn

**ABSTRACT**

In the Leizhou Peninsula - northern Hainan Island region, South China, there were at least six large-scale volcanic eruptions in the Quaternary period. After a volcanic eruption each time, the surface was covered by basalitic rock. Under the tropical climate, the basalt was intensely weathered and finally developed into laterite. When the next volcano erupted, however, the laterite formed on the surface would be covered by a new layer of basalt. In this way, a unique sequence of multiple cycles of basalt alternating laterite was formed.

Two sections composed of modern laterite—basalt—buried paleo-laterite were collected in the Yingfeng Ridge and Qujie Town in Xuwen County of the Leizhou Peninsula, Guangdong Province, South China. The physical and chemical characteristics of each layer of the sections were studied. There were significant differences in various characteristics between the modern laterite and buried paleo-laterite formed in the Middle Pleistocene. The colors, pH, magnetic susceptibility (χlf), free iron (Fed), and total iron (Fet) of the modern laterite are 10YR4/4, 4.69, 1500×10−8 m3 kg−1, 101.2 mg g-1 and 211.1 mg g-1 on average; and these of the buried paleo-laterite are 10R4/8, 4.53, 226×10−8 m3 kg−1,155.5 mg g-1 and 218.6 mg g-1 on average, respectively. The molecular ratios of SiO2/Al2O3, SiO2/(Al2O3+Fe2O3) and (CaO+MgO+K2O+Na2O)/Al2O3, and Fed/Fet of the modern laterite are 2.07, 1.41, 0.017 and 0.479 on average; and these of the paleo-laterite are 2.06, 1.39, 0.012 and 0.711 on average, respectively.

The curves of trace element distribution of the modern laterite, basalt, and paleo-laterite of the sections are completely consistent. This indicates that the laterites are derived from the same source of basaltic rock. Compared with the modern laterite, the paleo-laterite formed in the Middle Pleistocene is redder in color hue and significantly higher in pedogenic Fe oxides, indicating stronger chemical weathering. χlf value of the paleo-laterite is lower, probably due to the effect of high-temperature demagnetization when it was covered by hot lava.

The basalt-laterite sequence in the Leizhou Peninsula perfectly reserves the paleo-laterite in the Middle Pleistocene, reflecting that the climate in the low-latitude tropical region was more humid and warmer in the Middle Pleistocene, when the weathering and pedogenic effects on the surface were much stronger; by the Late Pleistocene, the climate turned cooler and the development of laterite on the surface was weakened. This also suggests that there have been significant climate changes even in tropical regions since the Middle Pleistocene.

# The Final Stage Of Loess Accumulation In The Glacial Region Of The Last Glaciation And Its Reflection In The Properties Of Modern Soils: A Case Study Of Northwestern Russia.

**A. Leontev[1], A. Rusakov[1], A. Makeev[2], and N. Mokievskiy[2]**

**ABSTRACT**

In the region of the last (Valdai, Ostashkovo) glaciation in the northwest of the Russian Plain, Holocene soils form mainly on glacial deposits. During large-scale soil mapping of fallow lands in the Leningrad Region in 2022–2024, we identified soils with silty, carbonate-free, boulderless parent materials atypical for the region. Based on morphological analysis and particle-size distribution, they are similar to loess-like loams (loessoids) of the periglacial zone.

Said layers usually form a thin upper mantle (up to 0.6 m) overlying till or glaciolacustrine clays. In other cases, they can be encountered as a weakly differentiated stratum (visible thickness up to 1.5 m). At one of the study sites (former "Volna" state farm), a series of catena profiles showed that a homogeneous silty stratum (possibly cover loam) has a consistent thickness over 100 cm and lateral extent along the slope. It overlays sorted, silty loamy sands, sometimes with sand interlayers. Morphological variation in soil profiles is weakly expressed.

The lack of correlation with specific landforms may be explained by local supply of silty material via aeolian transport from the zone of a pulsating retreating glacier during the Late Glacial. Such deposits can be considered a niveo-aeolian variant of loessoids.

Recent studies in Fennoscandia indicate that aeolian activity intensified during glacier retreat (14.4–13.8 ka BP). Recent data from Sweden (Gothenburg area) also confirm the presence of a thin (0.15–0.80 m) loess mantle ("flygmo") deposited about 14 ka BP.

In conclusion, the study confirms the presence of Late Glacial loess-like mantles in the northwest Russian Plain, attributed to local niveo-aeolian processes during glacier retreat. This finding aligns with the regional paleogeographic model of Fennoscandia and highlights the significant role of aeolian activity in the area's postglacial sedimentogenesis. Further research, including absolute dating, is required for detailed chronological and genetic analysis.

**ABSTRACT**

The forest-steppe is among the most complex and climatically sensitive ecosystems of the Northern Hemisphere, where closed-canopy forests and open steppe communities coexist across the Eurasian forest-steppe zone extending from eastern Europe to China and covering ~2.9 million km². During the Holocene, the southern limit of forest distribution fluctuated repeatedly, retreating northwards during more arid phases and advancing southwards under more humid conditions. However, the spatio-temporal patterns and drivers of these shifts remain poorly understood.

Here we present a novel, original palaeopedological methodology that uses infilled burrows of fossorial mammals ("krotovinas") preserved in Chernozems as a widely available, soil-based palaeoarchive in arid ecosystems. Using a multi-proxy approach integrating soil properties with pollen analyses (incl. non-pollen palynomorphs), and AMS radiocarbon dating, we demonstrate that krotovina infills provide a robust and scalable archive for reconstructing Holocene vegetation and moisture dynamics across the forest-steppe and steppe zones.

We investigated seven sites in Belgorod Oblast (East European Plain), where Chernozem profiles contain abundant krotovinas attributed to the greater blind mole-rat (Spalax microphthalmus). We sampled 27 krotovina infills and collected 8 surface References samples. Soil organic carbon (SOC) was measured for all samples, and the chronology was established using AMS radiocarbon dating of the SOC fraction from 14 infills. Pollen analysis, supplemented by identification of non-pollen palynomorphs, was conducted for the entire dataset. The studied krotovina infills span ~8.4–2.3 ka cal BP, and stratigraphic and pedological patterns support this temporal ordering: older infills occur deeper in the profiles and exhibit lower SOC, paler colours, and more diffuse boundaries. All infills contained pollen in sufficient quantities and with adequate preservation to enable reliable vegetation reconstruction. Surface samples reflect disturbed meadow-steppe vegetation, whereas krotovina spectra span a broad range from relatively forested to dry steppe communities. Ordination of krotovina spectra along SOC and age gradients indicates major shifts in vegetation cover, from Artemisia-dominated xerophytic steppe to wetter, warm-climate meadow-steppe with increasing forest cover. From ~4900 cal yr BP onwards, spectra increasingly reflect anthropogenic landscape transformation, with clear signals of pastoralism and vegetation disturbances.

Overall, krotovina infills preserved in Chernozems provide a palaeoarchive that fills the gap between wetland records and limited palaeosols. This methodology has strong potential for reconstructing vegetation and land-use dynamics across the Eurasian forest-steppes and the North American prairies.

**ABSTRACT**

The black soil region of Northeast China has revealed widespread silica-clay composite layers that constrained crop root, yet their origin—chemical weathering versus biological enrichment remains debated. Here, a sequential chemical extraction method and biogeochemical coupling analysis were applied to demonstrate that the total Si pool in black soil consists predominantly of Si (residual silicon ($Si_{res}$): 96.02%−97.34%), with non-crystalline silicon ($Si_{noncry}$) accounting for 2.66%−3.98%. Silica neoformation accumulation layers demonstrated marked enrichment in $Si_{res}$. Overall, soil pH, organic carbon content, and bulk density regulated the vertical differentiation of Si fractions by influencing silicate dissolution-precipitation dynamics and cementation processes. A quantitative model of Si biogeochemical ratio was proposed and used to quantify interaction intensity between biological and chemical processes. Holocene climatic cycles drove silicate migration and transformation, with chemical weathering dominating during glacial periods and biological processes intensifying during interglacial phases, revealing co-dominant roles of biological and chemical processes in forming silica neoformation accumulation layers. This study clarifies that climate-driven biogeochemical coupling shapes silica neoformation accumulation layers in black soils, providing a theoretical basis for understanding pedogenesis.

# Radiocarbon dating: new approaches in soils and paleosols – are these new opportunities or problems?

**Elya Zazovskaya**

*Center for Applied Isotope Studies, University of Georgia*

elya.zazovskaya@uga.edu

**ABSTRACT**

The radiocarbon method is actively used in soil science and paleopedology to determine soil age, carbon exchange rates in the soil-atmosphere system, organic matter dynamics, and geochronological reconstructions. The first data on the radiocarbon age of soil organic matter (SOM) were published in 1959 by R. Simonson, who determined the age of meadow soils in North Dakota to be approximately 1,300 years before present (BP). Over the past nearly 70 years, radiocarbon dating has become a routine procedure in soil science, especially in paleosol science. A large array of $^{14}C$ data for soils from different regions has been accumulated, and an International Soil Radiocarbon Database, ISRaD, has been established (http://www.soilradiocarbon.org).

The development of accelerator mass spectrometry (AMS) has enabled soil scientists to date individual SOM fractions, biomarkers isolated from buried soils, date soil carbonate formations layer by layer, and date paleosols with low carbon content. However, as in previous years, the interpretation of data obtained for soils is not always unambiguous. When interpreting the data, it is important to understand the source of carbon in the dated sample, whether the dated pool is homogeneous or heterogeneous, and whether the system was open, open-closed (which applies to most dated soils), or closed. In most ecosystems, SOM is best viewed as an open system where new carbon is constantly being added via photosynthesis and organism death, while older C is constantly removed by microbial decomposition. These processes operate concurrently on the bulk

SOM pool over a range of timescales from minutes to millennia. The exchange rate of C from organic soil pools is difficult to quantify due to this wide range of timescales, and $^{14}C$ provides one of the few tools for determining in situ soil C dynamics in both disturbed and undisturbed ecosystems.

Depending on the research objectives, different approaches are chosen to isolate soil fractions for dating. It should be acknowledged that at present there is no single approach to dating soil organic matter or a universal dating fraction that would be effective in all soil studies. To interpret the age of soils based on $^{14}C$ data, it would probably be necessary to fractionate the sample into components that differ in their mechanisms of organic matter stabilization.

Despite the numerous new analytical possibilities in $^{14}C$ dating soil organic and inorganic carbon that are opening up to us, we must first and foremost adopt the perspective of a soil scientist and carefully design our research before simply obtaining a radiocarbon data.

# Soil-Permafrost Complexes of the Russian North-East Arctic Accumulative Sea Coasts: Structure, Properties, Diagnostics, Ecological Functions

**Aleksei V. Lupachev***

*Institute of Physicochemical and Biological Problems of Soil Science, Russian Academy of Sciences (Soil Cryology Laboratory, Puschino, Russia)*

*E-mail a.lupachev@gmail.com

**ABSTRACT**

The soils and the upper permafrost on the coasts of Arctic seas remain poorly studied due to their hard accessibility but obviously demand thorough studying in the nearest future. The large length of the coastline, the diversity of coastal geomorphic features, landscapes, sediments, the character of tidal and surge phenomena, and the salinity of the sea determine the formation of a wide range of permafrost-affected soils. The morphology of soils on the Arctic coasts are complicated by the severity of the climate, cryogenic processes, and specific biota. A significant part of the coasts here belongs to the accumulative coasts with very gentle slopes (e.g. in the Russian North-East Arctic region). This leads to the penetration of surge water to the inland for tens of kilometers; seawater feeds numerous small thermokarst lakes, flooded swampy meadows, and cryogenic polygons, which also affects soil and permafrost formation here.

Our study suggests distinguishing three major areas of sea-soil-permafrost interaction on the accumulative sea coasts.

*Weakly developed permafrost-affected marsh soils* are characterized by the weak development of the sandy-loamy profiles by postlithogenic pedogenesis, close occurrence of the permafrost aquiclude, and watering of the profiles. The saturation of soils with water during tides and surges prevents the active entry of fresh portions of salts into the soils and their redistribution within the soil profiles. Often the maximum content of soluble salts in the profile is shifted to the suprapermafrost horizon. The material of these horizons may remain in a thawed state (without ice) at subzero (up to –1…–2.5°C) temperatures. The closest WRB analogue here is most probably *Tidalic Arenosols gelic (loamic)*.

*Permafrost-affected marsh soils* of Arctic coasts display quite definite relationships between their morphology and properties and the distance from the sea, the development of cryogenic polygonal microtopography, waterlogging of the profiles, and vegetation. Peat horizons bear signs of siltation, and deeper mineral layers are differentiated into genetic horizons. Their properties and structure retain features inherited from previous, more active stages of synlithogenic soil formation, which are superimposed by the influence of modern postlithogenic soil formation. The closest WRB analogue here is *Tidalic Gleysols gelic histic*.

*Maritime permafrost-affected soils* have the morphology of the zonal soils (mainly Cryosols and Gleysols). The influence of the sea on them is manifested by the presence of some features that do not develop into separate genetic horizons and is associated with the aerial transport and deposition of salts and plant detritus from tidal flats and tidal marshes and an increased soil moistening owing to the proximity of the sea. The closest WRB analogue here is *(Proto-)Salic Cryosols/Gleysols chloridic/sulphatic*.

# Suggestions for Classifying Soils of the Retrogressive Thaw Slumps Impact Zone in Future Russian and International Soil Taxonomies

**Alexander P. Ginzburg*, Alexey V. Lupachev**

*Soil Cryology Laboratory, Institute of Physico-Chemical and Biological Problems in Soil Science RAS, Pushchino, Russia*

*ginzburgap@yandex.ru

**ABSTRACT**

Thermodenudation is a process of permafrost sediments destruction and redistribution. It activates due to climate warming and humidization, and initiates as well by some other natural and technogenic factors. Retrogressive Thaw Slumps (RTS) are widely distributed across plain and mountainous permafrost zone. Their properties depend on local conditions. Common impacts of all RTS are dramatic shifts in ecosystem structures (including soil cover and upper permafrost) (Nesterova et al., 2024).

There is a lack of research on soil dynamics under RTS impact. No standardized soil profile descriptions, no soil diagnostic horizons, and no approaches to classification of such soils exist at the moment. Basing on personal experience of permafrost-affected soils field studies, we began filling this gap.

The principal scheme of synlithogenic soils development under RTS impact includes 4 stages: 1) accumulation of organo-mineral material; 2) stabilization and initial drainage of soil surface (initial algae-moss-lichen vegetation); 3) full soil drainage (graminoid-grass vegetation); 4) transition to postlithogenic development (moss-shrub tundra). These stages could change each other consequently or repeat cyclically in case of thermodenudation reactivation. The diagnostic horizon of such soils is the "thermodenudationally-accumulated material" (RAtd) – mixed, water-saturated (incl. thixothropy) organo-mineral horizon that could also include fragments of soil organic matter, Fe, Mn and S compounds' new formations etc. Its structure, texture, physico-chemical and biological properties vary depending on the parent material properties. We suggest introducing the new sub-type – *"Thermodenudationally-accumulated stratozems"*, – into the further versions of the Russian Soil Taxonomy within the stem of synlithogenic soils, stratozems order. If the RAtd thickness do not exceed 40 cm, the sub-type *"Thermodenudationally-stratified"* should be used for soils from other stems and orders. In implement to the WRB we suggest changing the list of diagnostic properties for the *"solimovic"* qualifier, and to make it possible to use it for slumps formed by sediments of marine-, lacustrine-, fluvial- etc. origin (incl. perennially frozen).

# Spatiotemporal Variations of Soil Hydrothermal Processes and Their Association with Mattic Layer Rupture in Alpine Soils on the Qinghai-Tibetan Plateau

**Yun-Zhi Wang[1*], Zhuo-Dong Jiang[1], and Fu-Jun Sun[1]**

[1] *Yun-Zhi Wang (College of Land and Environment, Shenyang Agricultural University, Shenyang,China)*

[1] *Zhuo-Dong Jiang (College of Land and Environment, Shenyang Agricultural University, Shenyang,China)*

[1] *Fu-Jun Sun (College of Land and Environment, Shenyang Agricultural University, Shenyang,China)*

*wangyunz9@163.com

**ABSTRACT**

The mattic layer (ML), a dense root-soil matrix formed predominantly by Kobresia sedges, constitutes a keystone subsystem governing ecosystem functioning across 2.5 million km² of the Qinghai-Tibetan Plateau. However, the ML rupture has emerged as a widespread structural failure threatening this vital ecological barrier. Recent studies suggest that ML rupture is driven by synergistic anthropogenic and natural factors, yet the underlying mechanisms, particularly the role of soil thermal-hydrological processes, remain poorly understood. Therefore, this study explored relationships between soil thermal-hydrological dynamics and ML rupture distribution using multi-scale analysis method in a typical ML rupture area on the QTP. A total of 10 in-situ monitoring instruments were set up across different topographic positions and vegetation cover types, and soil temperature and moisture data from 0-50 cm depth with 10 cm interval were hourly recorded, respectively. The spatial-temporal variation of soil thermal-hydrological conditions were mapped using 13 related environmental variables that derived from high-resolution UAV measurements. The spatial distribution of ML ruptures was overlaid with soil thermal-hydrological maps in pixel level. A total of eight core landscape metrics were employed to quantify ML rupture severity and its relationship with thermal-hydrological conditions. Statistical analyses combined Welch's t-test and Cohen's d effect size revealed significant differences in soil temperature and moisture conditions between ruptured and intact ML areas, with the most pronounced disparities observed during critical months including January, April, and September. Results also showed that ML rupture is primarily driven by intense soil freeze-thaw alternation. Freeze-thaw intensity decreased significantly with depth, with surface layers exhibiting the most active freeze-thaw dynamics. Spearman correlation analysis revealed that freeze-thaw cycling frequency exhibited the strongest association with rupture severity (r=0.66 with largest patch index, r=0.76 with nearest neighbor distance). These findings provide quantitative evidence supporting the hypothesis that ML rupture occurrence and aggravation was correlate to the thermal-hydrological spatial and temporal variations, especially the area with intense and frequent soil freeze-thaw alternation are more fragile. The results can be used to develop space-time precision conservation strategies in degraded alpine pasture ecosystems.

* samohvalov.nd@yandex.ru

**ABSTRACT**

Soils and upper permafrost horizons are complex and dynamic systems in modern climate change especially in such remote permafrost-affected areas as Eastern Chukotka, where climate-derived permafrost dynamics are obvious. Here we represent one of the first ever soil cover descriptions at Eastern Chukotka coastal plains, located in continuous permafrost zone. We also report about key features of the spatial distribution of the upper permafrost horizons and their relationships with soils. This research took place in August 2025 along the transect through different geomorphological levels – fluvio-glacial plain, marine and glacial-marine terrace, marine terrace and alluvial terrace. The most common soils are Turbic Oxyaquic Histic Coarsic Cryosols (Clayic/Loamic, Thixotropic) and Oxygleyic Histic Gleysols (Clayic, Loamic, Skeletic). The main feature of interaction of permafrost-affected soils and underlaying permafrost layers is an evidence of the ice-rich layers, also known as transient and intermediate layers. They have specific cryogenic structures (suspended and reticulate) with visible ice exceeding 50%. For the reason these layers protect permafrost from accelerating climate warming (Shur et al., 2005). This layer thickness was 53–165 cm depending on geomorphological position and sediment's texture. Transient and intermediate layers include some visible pedogenic features – Fe and Mn oxides and coarse organic matter fragments. These features were transported through soil profiles and buried in transient/intermediate layers via processes of cryoturbation and vertical migration after chemical/physical leaching.

**ABSTRACT**

The stability of permafrost and its vast carbon stock is regulated by the insulating properties of soil organic carbon (SOC). However, intensifying wildfires across the Arctic and boreal regions are removing the protective soil organic layer, which may trigger a powerful feedback that accelerates thaw, yet the pan-Arctic scale of this threat remains unknown. Here, we combine an empirical model of permafrost probability, constrained by air temperature and SOC, with a pan-Arctic synthesis of SOC combustion and post-fire SOC recover rate, and projections of future climate and fire activities. We find that under a low-emission scenario (SSP1-2.6), fire-induced SOC loss, considering both combustion and post-fire recovery, reaches 20 ± 4 Pg C by 2100, which drives an additional permafrost loss of 3.6 ± 0.8 million hectares. This fire-driven permafrost loss is less pronounced under high-emission scenarios, where rapid atmospheric warming is the predominant driver. Under SSP1-2.6, every 1 km² of increased burned area is projected to cause a 0.25 km² of permafrost loss, highlighting the process's efficiency. Our results reveal a critical fire-SOC-permafrost feedback that disproportionately undermines permafrost stability in scenarios that achieve moderate climate mitigation. Without considering the effects of wildfire on soil thermal properties, current Earth system models likely underestimate future permafrost degradation.

# The $CO_2$ and $CH_4$ fluxes from the epiphytic lichen Evernia mesomorpha collected in boreal forest underlain by cryosols

## ABSTRACT

The study examined greenhouse gas ($CO_2$ and $CH_4$) fluxes from the surface of the epiphytic lichen (EL) Evernia mesomorpha, which is typical for larch forests that are underlain by permafrost. The research was conducted near the Tura Experimental Station, located in the Tura settlement within the Krasnoyarsk region of Russia. The site is located in the northern part of Middle Siberia, in the middle reaches of the Nizhnyaya Tunguska River (64°18′ N, 100°11′ E). According to Russia's soil-geographic classification, the area is part of the Central Siberian province, which features permafrost-affected taiga soils predominantly consisting of cryozems. The development of these soils is influenced by the region's cold, humid climate and the presence of shallow permafrost, which thaws to a depth of approximately 70 cm by the end of summer. The larch stands in this area are relatively sparse, allowing solar radiation and winds to impact the surface [2, 3].

ELs are poikilohydric organisms that activate defense mechanisms to safeguard their tissues and metabolic processes from dehydration-induced damage. Unlike higher plants, lichens lack the ability to regulate the moisture entering or evaporating through their cells via stomata. As a result, they experience frequent cycles of wetting and drying (poikilohydry), which are influenced by the availability of dew, rain, snow, or high air humidity [1]. This capacity of ELs is particularly intriguing when assessing the effects of varying hydration levels in lichen thalli on greenhouse gas (GHG) fluxes, especially $CO_2$ and $CH_4$.

In this study, we examined the impact of varying water content in the thallus of E. mesomorpha on greenhouse gas ($CO_2$, $CH_4$) fluxes during an incubation experiment. Samples of E. mesomorpha were collected in June from the branches of larch trees (Larix gmelinii). The samples were moistened with artificial rainwater to achieve thallus moisture levels of 50%, 100%, 200%, and 400%, and then incubated in triplicate within glass flasks under light for 3 days. Gas samples were collected daily through a gas-tight septum at both the beginning and end of a 2-hour measurement period and analyzed immediately for $CO_2$ and $CH_4$ content using a Picarro 2201-i.

It has been demonstrated that the moisture content of the EL thallus influences both the magnitude and direction of GHG fluxes from its surface. Specifically, the E. mesomorpha thallus increases carbon dioxide ($CO_2$) emissions when exposed to excess moisture, while a decrease in thallus moisture leads to increased methane ($CH_4$) production and $CO_2$ photoassimilation. Furthermore, the branch's exposure (southwest or northeast) affects the EL surface's GHG flux variability.

**ABSTRACT**

Currently, much research focuses on the carbon (C) cycle and temperature-dependent processes in high latitudes that cause climate change, while there is insufficient information about the role of lichens, including epiphytes (EL), in the C balance of such ecosystems, especially in the continuous permafrost zone of Middle Siberia. Therefore, the aim of this study was to assess the actual and potential fluxes of carbon dioxide ($CO_2$) and methane ($CH_4$) in one of the most common lichen species, *Bryoria simplicior* (Vain.) Brodo et D. Hawksw., inhabiting larch trees (*Larix gmelinii* (Rupr.) Rupr.) in the continuous permafrost zone of Central Siberia (Tura settlement, Krasnoyarsk region, Russia). Seasonal studies (from mid-June to August 23, 2025) of greenhouse gas (GHG) fluxes from *Bryoria* transplants showed $CO_2$ fluxes ranging from -627 mg $CO^2$ $m^{-2}$ $h^{-1}$ ($CO_2$ photoassimilation) to 1011 mg $CO_2$ $m^{-2}$ $h^{-1}$ (predominantly $CO_2$ release). Regarding methane, its consumption by *Bryoria* transplants was mainly detected during the growing season. Although methane release cases were observed at high levels of lichen thallus hydration (over 600%) due to prolonged rainfall (e.g., DOY 177 and 179). The incubation experiment aimed to assess potential fluxes of GHGs under polar day conditions. To simulate these conditions, we used a photoperiod of 12 hours of light at +20°C and illumination (PAR=100-200 µmol photons $m^{-2}$ $s^{-1}$) and 12 hours at 10°C and supplemental lighting at PAR=10 µmol photons $m^{-2}$ $s^{-1}$. Thallus water content was 50, 100, and 200%. Incubation in light conditions revealed the influence of the tree stem exposure (northern or eastern) where the ELs were growing on the $CO_2$ flux rate (up to 136 µg C-$CO_2$ $g^{-1}$ $h^{-1}$) only at a thallus water content of 200%. During the 3-day aerobic incubation of *Bryoria* in light conditions, methane emissions were observed up to 2.06 ng C-$CH_4$ $g^{-1}$ $h^{-1}$ at all levels of thallus water content. It is expected that new data on ELs GHG fluxes in the context of varying thallus moisture due to changes in precipitation patterns will allow for a review of overall GHG flux estimates in forest ecosystems, thereby improving our understanding of current processes and future projections.

**ABSTRACT**

The uniqueness of the cryolithozone's soil cover and ecosystem is determined by their properties formed in permafrost zones and exposure to harsh climatic conditions for at least 9 months. Here, soil freezing processes have a significant impact on soil formation, manifesting themselves in physical fragmentation during freeze-thaw cycles, coagulation, and crystallization. The influence of these processes on the biological activity of cryolithozone soils is enormous. The functioning of microbial communities in the north is influenced by temperatures, low pH values, and the specific composition of organic residues entering the soil. Of particular interest in this region is the activity of soil enzymes, which perform a variety of functions in the soil: decomposition of mineral and organic matter; maintenance of soil homeostasis; participation in humus biogenesis and soil metabolism under unfavorable conditions for microorganisms. The aim of our study is to characterize the biological activity of podzols in the south of the Yamal Peninsula.

The study subjects were podzols collected in the south of the peninsula—raw-humus podzols and turbated peat podzols, represented by natural variants and anthropogenically transformed "analogues." Soil samples were collected in the summer of 2023, both within the Arctic Circle, north of Novy Urengoy, and in the city itself.

Most of the territory is occupied by tundra with characteristic cryogenic landforms: frost mounds (pingos), thermokarst funnels, and medallion spots. The parent rocks are sandy and lacustrine-alluvial deposits with low iron content.

In all soils, the activity of catalase and invertase decreases with depth, which is associated with a decrease in water-soluble organic carbon and labile humic substances, which are a substrate for soil microorganisms. Catalase and invertase enzyme activity is characterized as "very poor" and "poor" in all horizons of the studied soils. The only exceptions are two horizons: the peat horizon of the gley peat-podzol and the Oao horizon of the raw-humus podzol.

Maximum urease activity is determined in the E horizons of the abrazems. In the gley peat-podzol, maximum urease activity is confined to the peat horizon. Dehydrogenase activity was diagnosed only in three horizons: T2 of gley peat-podzol, O of coarse-humus podzol, and E horizon of alfehumus abrazem.

# Landscape Conditions of Soil Formation in Drained Lake Basins of the Russian European North

**ABSTRACT**

A study of the spatial differentiation of landscapes and soil cover in the drained basins of the Bolshezemelskaya Tundra has revealed their significant diversity. The investigated basins are divided into two main groups: those with peat soils and those with mineral ones. Peat basins are differentiated by their geocryological conditions and soil cover composition. Among them, drained lake basins with permafrost-affected and seasonally frozen peat soils are distinguished. Mineral basins are divided according to their degree of drainage/wetland status and the soil composition of the coastal sites of lake terraces. Among the mineral ones, waterlogged and drained basins with peat-covered shores, as well as waterlogged basins with mineral shores, are identified. Basins with peat soils are confined to areas of permafrost peatlands. The presence of mineral soils in the basins is determined by a number of factors: a significant proportion of mineral soils in the coastal terraces and their low degree of peat formation; good current drainage and complex, rugged relief of the basin floor; a high shoreline sinuosity coefficient. Favorable conditions for waterlogging often develop in basins with mineral soils. The water saturation of the Histic soils in these basins inhibits the formation of near-surface permafrost. The study of the facies and soil diversity of the lake-bog landscapes led to the derivation of landscape-soil formulas. In a comparative analysis of the landscape-soil conditions in the basins and the surrounding areas, these formulas form "equations." The use of landscape-soil "equations" makes it possible to effectively analyze the landscape conditions and soil cover of the drained basins with their subsequent differentiation. Thus, the formation of various subgroups of drained basins is due to a complex of factors determined by the composition of the coastal terrace sites, the morphometric characteristics of the lake basins, and their landscape position. The complex spatial changes of these factors form a landscape-soil continuum, which, using the proposed «equations» describes a gradual transition from basins with peat soils to those with mineral soils.

# Features of Soil Formation in Khasyreys (Tundra Thermokarst Depressions)

**Alexander V. Pastukhov[1*], Dmitry A. Kaverin[1], Svetlana V. Deneva[1], Stanislav V. Yakubenko[2], and Andrey V. Chaburov[2]**

**ABSTRACT**

Tundra thermokarst depressions (Khasyreys) – former lakes – are widespread across the lowland tundra. Khasyreys generate as a result of permafrost degradation, where ground ice melts, the soil subsides, and a closed depression forms in place of the lake. This process is dynamic and has become increasingly active due to climate change. Furthermore, as part of Soviet programs to create meadows in the tundra as a forage base for agriculture, thermokarst lakes were artificially drained.

Two drained thermokarst lake depressions in the Bolshezemelskaya Tundra (Piatomboy-Glad' locality) were selected to study the specific features of the structure, properties, and temperature regimes of the soils. These khasyreys differ in their genesis (natural and artificial drainage) and the lithology of their bottom sediments (mineral with clays and sands, and organo-mineral, respectively).

The characteristics of the soil cover and soil properties are determined by the composition of the parent materials. In Khasyrey 1 (naturally drained with mineral sediments), soils typical for the region formed: Histic Reductaquic Cryosols and Gleyic Arenosols (Gelic). In Khasyrey 2 (artificially drained, with organo-mineral sediments), soils unique to the tundra occured: Sapric Cryic Histosols (Mineralic) and Gleyic Fluvisols (Arenic, Folic). The presence of humus-stratified mineral horizons is explained by the accumulation of silty material in the peat-mineral deposits during the period they were submerged (until 1979). The peat horizons are similar to those in Fibric Histosols on peat plateasus in tundra.

The physicochemical properties of the soils correlate with their genesis. All soils have an acidic reaction and a low/medium base saturation. The soils of Khasyrey 2, including the organogenic Sapric Cryic Histosols (Mineralic), are characterized by high ash content (40-50%), which is associated with siltation during the lake's existence. The carbon content is highest in the Sapric Cryic Histosols (Mineralic) (20-30%); however, the C/N ratio (16-19) indicates a relatively low enrichment of carbon with nitrogen.

The soil temperature regimes in the basins also differ significantly. The Gleyic Arenosols (Gelic) are characterized by deep seasonal freezing, significant summer warming, and intense winter cooling (a cold mid-depth permafrost profile). The Sapric Cryic Histosols (Mineralic) have a milder temperature regime with a shallow active layer, but with permafrost close to the surface (a cool shallow permafrost profile). The thick peat layer acts as a thermal insulator.

Cryogenic processes play a key role. The permafrost-affected soils in both basins belong to different types: in Khasyrey 1, they are "ecosystem-modified" (formed in a cold climate and preserved due to a thin organogenic horizon); in Khasyrey 2, they are "ecosystem-protected" (generated under colder conditions and preserved due to a thick, thermally insulating peat-mineral layer).

Thus, the structure, properties, and thermal regime of soils in drained lake depressions (Khasyreys) are determined by the lithology of the bottom sediments and the history of landscape evolution. The presence of organogenic horizons of varying thickness is a key factor providing protection for the permafrost from thawing.

*[4]Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, 610042, Chengdu, China*

**ABSTRACT**

In the context of climate change, the direct impact of temperature and precipitation on the start of the growing season (SOS) and carbon uptake on the Qinghai-Tibet Plateau (QTP) is well documented, yet the potential influence on spring soil moisture return (SMR) dynamics from freeze to thaw remains insufficiently understood. Here, we integrated multi-source data from 32 observing sites over QTP (2003-2024) and proposed a novel framework to quantify the removal degree of evapotranspiration moisture limitation (REML) by hydrological processes. The REML effect induced by freeze-thaw-driven SMR and spring precipitation was decoupled and quantified as $E_{SMR}$ and $E_{prec}$, respectively. Across the study sites, $E_{SMR}$ contributed 20.7% ± 2.1% (mean ± SD) of the SOS advance since 2003, surpassing the effects of $E_{prec}$ and air temperature, underscoring the role of pre-freezing moisture return in advancing SOS in the following spring. At sites with active layer thickness (ALT) exceeding 2.2 m, the $E_{SMR}$ exhibited ~24% higher sensitivity to surface soil moisture compared to sites with thinner ALT. We found that, compared to the direct impact of spring precipitation, the augmentation of pre-freezing surface soil moisture by prior summer-autumn precipitation and the overwintering SMR more strongly advance the following year's SOS ($p < 0.01$). As ALT deepens, the influence of soil moisture dynamics in the middle and lower active layers, associated with permafrost degradation, may gradually weaken in regulating SOS. Overall, our results provide a new insight into the underlying mechanisms of the nonlinear regulation of SOS by multiple hydrological processes over permafrost regions.

**ABSTRACT**

Investigated post-agrogenic transformation of Plaggic Podzols in the Yamal region (Western Siberia, Russia) using a chronosequence approach (0–25 years of abandonment) and a long-term fertilized References site (>90 years of management). Elemental (CHN-O) analysis, solid-state $^{13}C$ NMR spectroscopy, PXRD, and multivariate statistics were applied to assess soil organic matter (SOM) dynamics under harsh climatic conditions (mean annual temperature −5.1 °C, <70-day growing season). Results show an initial increase in soil organic carbon (SOC) during early abandonment (5–10 years: 3.75–4.03%), followed by significant depletion after 25 years (2.15–2.27%). This decline is attributed to limited organo-mineral stabilization in quartz-dominated, sandy soils with low clay content (5.3–12.4%) and negligible reactive mineral phases. Continuous organic fertilization at the Yamal Agricultural Station sustained higher SOC (3.58–3.83%), balanced C:N ratios (19–20), and preserved labile alkyl-C (39.61%), demonstrating the critical role of external organic inputs in compensating for poor mineralogical protection. $^{13}C$ NMR revealed progressive molecular shifts: active fields were rich in alkyl-C (40.88%), while abandoned soils showed enrichment in O-alkyl-C (21.6%) and lignin-derived aryl-C (15.88%), indicating microbial processing and humification. However, without mineral binding, these recalcitrant compounds remain vulnerable. Freeze–thaw cycles further destabilize SOM by disrupting soil aggregates, a key physical protection mechanism in temperate zones but ineffective here due to cryogenic disturbances and weak organic binding. Principal Component Analysis linked SOC loss to declining nutrient retention (P, K, N), reduced cation exchange capacity (CEC: from 12.3 to 9.5 mEq/100g), and increasing oxidation of SOM (O:C ratio: from 0.68 to 0.83). Despite degradation trends, SOC/clay ratios remained above the 1:13 threshold, suggesting structural integrity has not yet collapsed. Trace metal concentrations were below pollution limits (PLI = 0.63; RI = 46.2), confirming minimal ecological risk. The findings underscore the fragility of SOM in Subarctic agroecosystems and emphasize that sustained organic amendments are essential to maintain soil fertility and carbon stocks under climate and mineralogical constraints.

**ABSTRACT**

Investigating the contributions of different lichen species to greenhouse gas (GHG) emissions and uptake is crucial for predicting the responses of cryospheric ecosystems to climate change, as epigeic lichens are a key component of ground cover in the Arctic. Furthermore, their role in the GHG balance ($CO_2$ and $CH_4$) remains poorly understood. This study was conducted in July 2025 at two sites in the Arctic tundra, underlain by continuous permafrost, near Dudinka in the Krasnoyarsk region of Russia: one site represented tundra (a shrub-lichen-moss tundra), while the other was a forest-tundra site (a larch open forest with shrub-lichen-moss cover, located on a site affected by fire 30 to 40 years ago), both based on Histic Turbic Cryosols [ 1]. GHG fluxes were measured in situ using a custom-designed transparent chamber connected to a Picarro G4301 gas analyzer. Measurements were taken from pure mono-species mats of dominant lichens (Cladonia spp., Flavocetraria nivalis, Thamnolia vermicularis, Nephroma arcticum, and Alectoria ochroleuca) as well as from bare ground. Testing for the normality of the residuals' distribution and the homogeneity of variances indicated the necessity of employing nonparametric analysis methods. Non-parametric tests, quantile regression, and PCA analysis were utilized to assess the influence of lichen taxon and moisture content and photosynthetically active radiation (PAR) on GHG fluxes.

The tundra site had the highest $CO_2$ flux from bare ground (2.06 µmol $m^{-2}$ $s^{-1}$). The $CO_2$ emission rates varied among the lichen species, with Cladonia (1.46 µmol $m^{-2}$ $s^{-1}$) and Nephroma (1.28 µmol $m^{-2}$ $s^{-1}$) having the highest rates and Flavocetraria (0.248 µmol $m^{-2}$ $s^{-1}$) having the lowest. Statistically significant differences in $CO_2$ fluxes were identified only between bare ground and Flavocetraria ($p<0.001$), indicating photosynthetic activity in the latter. A similar trend was noted at the forest-tundra site: $CO_2$ fluxes from Cladonia (3.04 µmol $m^{-2}$ $s^{-1}$) and Thamnolia (2.72 µmol $m^{-2}$ $s^{-1}$) were significantly higher ($p<0.0001$) than those from Flavocetraria, which showed a flux close to zero or negative (-0.159 µmol $m^{-2}$ $s^{-1}$), thereby confirming its occasional $CO_2$ uptake. All measured plots acted as sinks for atmospheric $CH_4$ at both sites (ranging from -0.0004 to -0.006 µmol $m^{-2}$ $s^{-1}$). On the tundra site, the most substantial $CH_4$ uptake was recorded from Alectoria and Nephroma, significantly exceeding the uptake by bare ground. On the forest-tundra site, $CH_4$ uptake increased in the order Cladonia > Flavocetraria > Thamnolia, with a statistically significant difference between Cladonia and Thamnolia ($p<0.01$). This study demonstrates that GHG fluxes from Histic Turbic Cryosols are strongly controlled by the dominant lichen species, which can reduce $CO_2$ emissions by up to 8 times and increase methane uptake by up to 15 times compared to bare ground. Therefore, predictive models of permafrost-carbon feedback under climate change must account for the projected shifts in lichen communities.

# Contrasting Geochemical Signatures of Groundwater and Peatland Waters in Permafrost Bogs of the European Russian Northeast

**Alexander V. Pastukhov[1,2*], Dmitry A. Kaverin[1], Sergei V. Loiko[2], Tatiana V. Raudina[2], Artem G. Lim[2], Rinat M. Manasypov[2], and Anna A. Gerber[2]**

[1] *Institute of Biology Komi SC UB RAS (Syktyvkar, Russia)*

[2] *BIO-GEO-CLIM Laboratory, Tomsk State University (Tomsk, Russia)*

*alpast@mail.ru

**ABSTRACT**

Large mosaic peatland complexes of heaved permafrost peat plateaus, thermokarst fens and thermokarst lakes comprise the dominant landscape components in the European Russian Northeast. Peat plateaus underlain by permafrost cover only about 20% of the Russian European cryolithozone but contain almost 50% of soil organic carbon stocks (SOC), which are considered to be vulnerable to microbial mineralization after permafrost thaw.

Two permafrost bogs were studied in the southern limit of the cryolithozone. At each site, water was sampled from a depth of 10 to 20 cm from the following landscape tracts: peat plateaus, adjacent fens, fens with open water, thermokarst lakes, and streams draining the peatland area. The concentrations of major and trace solutes were measured by methods developed for samples rich in organic matter and low-salinity waters by ICP MS (Agilent Technologies 7500 ce, Santa Clara, CA, USA) and TOC-VCSN (Shimadzu).

A statistical analysis was performed to identify the main distribution patterns of the measured physicochemical parameters (pH, temperature, redox potential - ORP), dissolved organic carbon (DOC), dissolved inorganic carbon (DIC), major ions, and trace elements across distinct natural landscape tracts of peatland complexes: peat plateaus (permafrost peat mounds), adjacent (non-permafrost) fens, fens with open water, thermokarst lakes, and streams draining permafrost peatlands.

The most pronounced pattern is a strong negative correlation is observed between pH and ORP – the more acidic the environment, the higher the oxidative potential. A continuum of the landscape tracts is observed from "clean" streams (circumneutral, reducing, influenced by groundwater) to "organic" fens (acidic, oxidizing, with atmospheric nourishment and a strong influence of organic matter). DOC is a key factor controlling the mobility of many elements. Strong positive correlations are observed between DOC and the concentrations of Fe and Al: DOC/Fe and Fe/Al ratios are low in streams and high in fens. DOC forms stable complexes with Fe and Al, leaching them from the peat profile. All REEs show a sharp (orders of magnitude) increase in concentration in fens compared to streams. This is a classic manifestation of organo-complexation. The concentrations of Mn, Zn, As, Cu, Pb are also significantly increase in the acidic, DOC-rich waters of fens. DIC correlates with total mineralization. The highest values of DIC, Ca, Mg, Na, and Sr are found in streams. This indicates feeding by groundwater interacting with bedrock.

Thus, the statistical patterns in the data clearly demonstrate two primary mechanisms governing the chemical composition of natural waters in the region: groundwater geochemistry (determines the composition of streams – circumneutral, reducing, dominated by major ions and bicarbonates) and peatland water geochemistry (determines the composition of fens and lakes – acidic, oxidizing, dominated by organic matter and associated metals and rare earth elements). Samples classified as stream reflect an integral chemical signal from the entire catchment. The stream water is a product of interaction with all the landscape facies and tracts it flows through:

water from fens with high DOC and REE enters the stream; water from peat plateaus also contributes; groundwater interacting with bedrock provides high levels of DIC and major ions. DOC acts as the primary geochemical mobilizer and transporter for a large group of elements in peatland landscapes. A stream serves as an indicator and integrator of the geochemical processes occurring within the multitude of facies in bogs.

**ABSTRACT**

Supraglacial debris forms distinct ecological interface on glacier surfaces, representing an early stage of soil development where organic matter accumulation and transformation reflect complex interactions between glacial and terrestrial systems. This study investigated the molecular chemical composition of supraglacial debris organic matter (SDOM) and its environmental controls using pyrolysis-gas chromatography-mass spectrometry on two debris-covered glaciers of Gongga Mountain, southwest China. Despite both glaciers share granite bedrock, they exhibit distinct characteristics in terms of glacier retreat speed, climate, vegetation types, and SDOM content. Pyrolysis products of SDOM identified 95 chemical compounds belonging to 12 molecular classes, which were grouped into eight primary categories: lipids, aromatics, terpenes, N-compounds, carbohydrate-derived, lignin-derived, phenols, and unidentified compounds. Lipids and aromatics were the dominant components, constituting 28.38% and 25.33% of the pyrolysis products, respectively. Spatial variations in SDOM composition were observed between the eastern (Hailuogou Glacier, HG) and western (Dagongba Glacier, DG) slopes, with DG exhibiting higher molecular diversity and abundance. Multiple environmental factors affected SDOM composition, including elemental composition (K and Na), nitrogen and phosphate contents, and debris texture (clay and silt content). The spatial distribution of SDOM characteristics showed systematic variations with elevation and aspect, reflecting the impact of temperature and humidity precipitation on early soil development processes. These findings demonstrate that SDOM composition and initial soil formation in these extreme glacial environments are driven by the combined effects of microbial activities and local environmental factors. Our findings provide new insights into the pedogenic trajectories of high-altitude soil-landscape systems under ongoing environmental change.

**ABSTRACT**

Understanding the fate of organic carbon in thawed permafrost is crucial for predicting climate feedback. While minerals and microbial necromass are known to play crucial roles in the long- term stability of organic carbon in subsoils, their exact influence on carbon persistence in permafrost remains uncertain. Our study, combining radiocarbon dating and biomarker analyses, showed that soil organic carbon in Alaskan permafrost had millennial- scale radiocarbon ages and contained only 10%–15% microbial necromass carbon, significantly lower than the global average of ~30%–60%. This ancient carbon exhibited a weak correlation with reactive minerals but a stronger correlation with mineral weathering (reactive iron to total iron ratio). Peroxidase activity displayed a high correlation coefficient ($p < 10^{-6}$) with $\Delta^{14}C$ and $\delta^{13}C$, indicating its strong predictive power for carbon persistence. Further, a positive correlation between peroxidase activity and polysaccharides indicates that increased peroxidase activity may promote the protection of plant residues, potentially by fostering the formation of mineral- organic associations. Tibetan soils contained 4-fold higher microbial residue-derived SOC than Alaskan soils, with fungal necromass three times higher than bacterial necromass, while fungal necromass in Alaskan soils exceeded bacterial necromass by an order of magnitude. In both regions, strong association of SOC and microbial necromass with short-range ordered minerals underscores the role of mineral−microbe interactions in SOC stabilization. Strikingly, peroxidase activity in Alaskan soils was 1 order of magnitude higher than in Tibetan soils and was tightly correlated with mineral-bound organic carbon. These findings suggest that peroxidase-driven $H_2O_2$ reduction represents a previously unrecognized mechanism of SOC stabilization in Arctic permafrost, with important implications for carbon−climate feedbacks under warming.

# Heterogeneity of cryogenic soil cover related to development of patterned ground of Kolguyev Island (Barents Sea)

**A. Shmatova**

*Department of Soil Geography and Evolution, Institute of Geography, Russian Academy of Sciences, Moscow, Russia*

a.shmatova@yandex.ru

**ABSTRACT**

Tundra soil cover is highly heterogeneous at the microscale due to the nearly ubiquitous development of cryogenic patterned ground, including bare-soil circles, stripes, polygons, hummocks, etc. In Russian pedological literature, this phenomenon is described using the terms *cryogenic micropatterns of the soil cover* and *cryogenic soil complexes*.

Cryogenic micropatterns often contain substantial amounts of buried organic matter, part of which may remain frozen; both the quantity and the quality of this organic matter depend on the morphology, shape, and genesis of the microstructure. Patterned ground and the related cryogenic micropatterns, being the result of the combined action of cryogenic and pedogenic processes, are sensitive to climate change. However, estimating soil organic carbon stocks in a highly heterogeneous soil cover is a challenge, as cryogenic soil microstructures possess a complex internal organization.

Thus, the purpose of this study was to assess the current diversity of cryogenic micropatterns and their spatial distribution, providing a basis for subsequent evaluation of soil organic carbon stocks and their potential dynamics.

We developed and tested a methodological approach for describing these micro-heterogeneous soil cover, with particular attention to the internal organization of cryogenic micropatterns. For this purpose, we introduce the term morphotype of a cryogenic micropatterns of the soil cover. During fieldwork on Kolguev Island, we described the patterned ground and associated soil micropatterns, characterized the conditions of their formation.

Nine morphotypes of cryogenic micropatterns were identified in the studied region (Shmatova and Goryachkin, 2025). The spatial distribution of these micropatterns across Kolguev's landscapes *was found* to be heterogeneous: each landscape was characterized by its own unique set, consisting of 2-6 morphotypes. It was also revealed that the degree of heterogeneity of soil cover does not correlate with the expressiveness of surface microtopography. The established dependence of the distribution of micropatterns on lithological and geomorphological conditions provide opportunities for spatial calculations of soil organic carbon.

# Needle ice - an antigravity mechanism of cryogenic transformation of soils

**G. Matyshak[1*], M. Chepurnova[1], V. Chernova[1]**

[1] *Soil Science Department, Moscow State University, Moscow, Russia*

*matyshak@gmail.com

**ABSTRACT**

The formation of needle ice is a widespread, easily observed, but least studied cryogenic process affecting soil properties. Needle ice (NI, pipekrakes) are cryogenic formations consisting of needles of ice up to 10-15 cm high, developing on the soil surface with soil material inside. NI is usually formed on the bare surface of soils due to the migration of soil moisture to the freezing front during night frosts due to the temperature gradient between soil and air. At the same time, active cryoturbation and mechanical transformation of the soil surface occur.

The aim of the study was to characterize the effect of needle ice on the soil properties of the north of Western Siberia (Nadym, Tyumen region, Yamalo-Nenets Autonomous District, Russia). The surface horizons of peat spot soils were studied in the field, and soil samples exposed to NI in a model experiment were studied in the laboratory.

In the field, the surface horizons affected by the NI (0-5 cm) and the underlying ones (5-10 cm) were selected from 5 peat spots. A sample of peat and loam (5-10 cm) was also taken for conducting an experiment in laboratory conditions. For the cultivation of NI, an installation was used that creates a temperature gradient and conditions for the growth of NI. 10 cycles of freezing and thawing of soil samples were carried out, each of which showed the growth of needle ice 3-4 cm high. In parallel, an experiment was conducted with the same samples without the growth of NI (control). The work investigated the general properties and dynamics of labile soil parameters (content of water-extractable carbon and nitrogen (WEOC), basal (BR) and substrate-induced respiration (SIR)).

The results of field studies have shown that the degree of decomposition and ash content increases (by 70%) in horizons exposed to NI. The intensity of BK increases by 40%, and WEOC and microbial biomass – by 2 times.

A laboratory experiment showed that after 10 freeze-thaw cycles, NI had a significant impact on the biological activity of peat soils. As in the field, BR and SIR increased significantly compared to the control (by 22 and 30%, respectively). The content of labile carbon changed slightly, while nitrogen decreased by 40%.

Thus, the formation of NI leads to increased microbiological activity, an increase in microbial biomass, and the rate of consumption of available organic matter, indicating accelerated mineralization of soil organic matter.

**ABSTRACT**

Urbanization is a global trend that leads to irreversible changes in vegetation and soil worldwide. The environmental consequences of urbanization are particularly evident in polar regions, where low temperatures and nutrient-poor soils hinder the restoration and development of ecosystems. The thickness of the seasonal active layer is increasing due to the current warming climate in Arctic cities. The snow-free period is getting longer, making it easier to grow more heat-loving plants (lawn grasses, trees) in polar cities. In the European Arctic, many cities are located outside the cryolithozone, where there is no permafrost. Alternatively, the area of permafrost has decreased, while the thickness of the active layer has increased. At the same time, the frost-free period often lasts less than six months, and stable snow cover remains for up to six months. We studied the morphological structures, chemical properties, and diversity of soils in long-term frozen natural soils (Albic/Entic Podzols and Histosols) and artificially constructed soils (Urbic Technosols) in recreational and residential zones of cities, as well as operating and abandoned settlements in the Kola Arctic Region (Apatity, Monchegorsk, Murmansk, Vaiga-Guba, and Teriberka). These settlements are located outside the permafrost zone. We also used materials from studies in Vorkuta and Naryan-Mar (in the Eastern European Arctic), Barentsburg and Pyramiden (in the Svalbard archipelago), and the Tikhaya Bay polar station (in the Franz Josef Land archipelago).

## ABSTRACT

Palsa mires are peat mounds formations located at the southern boundary of permafrost distribution and are vulnerable to climate change. Warming can accelerate the mineralization rate of organic matter, large reserves of which, including in a frozen state, have been accumulating for several millennia. Cryogenic processes (heaving, turbation, cracking) form a heterogeneous soil cover, which complicates its study. A key task is identifying factors that affect soil heterogeneity and carbon cycle parameters, including climate, geology, and biology interactions influencing ecosystem carbon dynamics.

The object of the study is a typical palsa mire complex, within which the following landscapes are located: frost mounds and bog depressions. A total of 110 sampling points were established across 4 $km^2$, where morphological descriptions of soils and geobotanical descriptions were carried out, hydro-thermal parameters of the soils and the thickness of peat horizons were measured, and at some points, $CO_2$ emissions were measured using the chamber method.

Two groups of soils predominate in the territory: oligotrophic peat soils (of various types) – Histosols, and Podzols. Histosols are found everywhere, the Podzols predominantly on mounds. Based on upper soil horizon temperature, two groups were identified: cool flat-palsa peatlands and warm depressions or large mounds. $CO_2$ emission from the soils of the study area varies greatly and is not linked to specific elements of the plant or soil mosaic. The average specific $CO_2$ emission rates for bog soils and peatlands are similar; therefore, the contribution of ecosystems to the total flux depends on their area.

Based on studies assessing carbon stocks in the soils of frost mounds and depressions, conducted within this study area, regression models were constructed to establish a quantitative relationship between peat thickness and carbon stocks for different landscapes. Analysis of data from mounds revealed two distinct clusters. The first includes areas with thick, dense peat and high carbon stocks, for which precise regression equations were developed. The second cluster consists of areas with small thickness peat of low and medium degree of decomposition, where carbon stocks are correspondingly lower; separate models were also developed for them. The depressions are homogeneous according to this criterion. The specific carbon stocks were 471 t/ha on the hummocks and 98.5 t/ha in the depressions.

As a result of interpreting satellite images of the study area, the contours of hummocks and depressions were delineated. After calculating the total areas ofthe typical landscapes, it was found that the total carbon stocks in the soils ofthe hummocks amount to approximately 103,000 tons, and in the depressions, about 7,000 tons.

# Climate-Induced Changes in Soil-Forming Factors and Processes in Permafrost-Affected Areas: Positive and Negative Trends (A Review)

**ABSTRACT**

A recent compendium of changes in climate parameters and their consequences for ecosystems and human society in cold regions of Russia (Edelgeriev & Ivanov, 2024), as well as relevant internet and published data on other permafrost-affected areas, was analyzed. Climate change, characterized by increased temperature, precipitation, and wind speed, is a notable phenomenon in these regions. However, the response of soil geocryological systems depends on the initial temperature of the permafrost, the depth of the organic layer, and other parameters. Frontal deepening and fractal deepening of soil profiles take place. The latter may be catastrophic, affecting not only the soil but also the landscape. Increased wind speed would intensify wind erosion in some areas and aeolian sand accumulation in others, which is important for sand massifs close to the Arctic coast.

A positive trend is the greening of the Arctic and the northward shift of the treeline. These trends increase biomass, activate carbon turnover in soils, and decrease reductive conditions in soils. Increased biomass productivity in forest stands would result in the northward shift of logging and the development of the forestry industry. However, the growth in the number and size of climate-induced wildfires is a major factor influencing vegetation and soil succession in forests in East Siberia and Alaska. All loamy soils represent various stages of post-pyrogenic development. The intensity and strength of fires determine plant succession types, active-layer thickness, cryoturbation intensity, gleying processes, and the reversibility or irreversibility of soil changes.

Agriculture is not widespread in northern regions, but it is a strong factor in Cryosol transformation because the quantity of agricultural lands is not decreasing but increasing due to the positive effects of climate change on the vegetative period. This can lead to both the deepening and disappearance of permafrost. However, the consequences for the soil depend heavily on the architecture of the cryosystems — ranging from slight positive changes in soils with low ice content to the complete destruction of the soil cover in ice-wedge polygon landscapes.

Therefore, our analysis shows that, in addition to the well-known infrastructure hazards, the negative trends in the consequences of climate-induced changes to permafrost-affected soils outweigh the weak positive trends in high latitudes.

**ABSTRACT**

Palsas (peat frost mounds) are recognized as important natural indicators of climatic changes (Olvmo et al., 2020). Of particular interest are those located in the heavily polluted industrial barrens near Monchegorsk. Despite the complete loss of vegetation and the covering of dark peat due to acid rain from a nearby metallurgical plant, a frozen core persists within these mounds. The persistence of permafrost in disturbed conditions makes this object a unique phenomenon, of interest for studying the factors ensuring its resilience to climate warming. To determine the causes of this phenomenon, a comparative study of the structure and properties of the peat soils (Cryic Histosols) of a palsa in an industrial barrens and in an undisturbed mire was conducted. The study involved geophysical measurements using ground-penetrating radar, core drilling, and analysis of samples from the active layer. Active layer thickness monitoring revealed seasonal dynamics, increasing from 20 cm in June to 70 cm in September. Our analysis identified three key factors contributing to the palsa's stability in the industrial wasteland: (1) Effective drainage. The mineral base of the peat deposit consists of sands, which provide good drainage. This is critical, as increased peat moisture promotes permafrost degradation (Martin et al., 2019); (2) Microclimate change. Due to the destruction of vegetation, winds have intensified and snow cover has decreased (Kozlov, Zvereva, 2007), which favorably affects the preservation of the frozen core in industrial wasteland. During the cold season, soil freezing accelerated (the temperature at a depth of 40 cm drops below 0°C two weeks earlier than on mounds with vegetation, and thaws 2–3 weeks later); (3) Impact of acid rain. Erosion of the peat has led to increased porosity of the active layer compared to normal conditions (void ratio 15.85 vs 8.83), which has enhanced its thermal insulation properties, for instance, the thermal conductivity coefficient (0.375 vs 0.458 W/m·K). Thus, a unique situation has developed on the Monchegorsk industrial wasteland – anthropogenic impact has generally led to a negative ecological effect, but at the same time has created conditions for the stability of the palsa's permafrost.

**ABSTRACT**

Arctic tundra soils store vast amounts of soil organic carbon (SOC), whose vulnerability to climate change is controlled by the relative partitioning between labile particulate organic matter (POM) and comparatively persistent mineral-associated organic matter (MAOM). Yet, the pedogenic and biogeochemical mechanisms governing this balance and stability remain inadequately constrained at the pan-Arctic scale. We have launched an international collaboration spanning Alaska, Canada, Northern Europe, and Greenland to address this gap. Mineral soils beneath the organic layer are being fractionated using a standardized size-density protocol. For each fraction, we quantify total organic carbon (TOC) and total nitrogen (TN) contents, stable isotopes ($\delta^{13}C$ and $\delta^{15}N$), C/N ratios, and an aromaticity index, thereby assessing organic matter quality and inferring fraction-specific stabilization pathways. Here, we present the compilation of these experimental datasets, integrated with a meta-analysis of published studies, to establish a comprehensive circumpolar database of POM and MAOM properties. Using this synthesized database, we aim to apply data-driven and machine-learning approaches (e.g., decision trees and random forests) to explore the climatic, edaphic, and biotic variables that predict SOC partitioning and fraction-specific chemistry. This framework serves as a foundation to identify when and where SOC is stabilized as MAOM versus retained as POM, providing a basis to anticipate SOC vulnerability under warming, altered snow regimes, and vegetation shifts. By uniting standardized fractionation protocols with scalable analytics, our efforts contribute to advancing pan-Arctic, mechanism-informed predictions of Arctic carbon fate in a rapidly changing world.

**ABSTRACT**

Thermal permafrost degradation promotes increasing $CH_4$ emissions from soils owing to either bacterial decompositon of thawing soil organic matter or release from thawing massive ground ice containing dissolved methane and gas bubbles. On the other hand, an observed increase in air and land surface temperature might lead to decreasing soil humidity and favoring methanotrophy in the active layer. Three monitoring sites were organized in 2021-2022 in typical landscapes of Central Yakutia, Northern Eurasia, to observe vertical distribution of $CH_4$ concentrations in gaseous phase of permafrost-affected soils. Air sampling was performed using soil pipe technique, described in (Smagin, 2005). Soil air inlets were installed at 0.2m, 0.4m, 0.6m, 0.8m and 1.0m depths along with plastic tubes going up to the ground surface, as shown in the figure. Soil air was sampled in plastic 50ml syringes, transferred to glass vials pre-filled with saturated NaCl solution and transported to the laboratory. Methane concentration in samples was measured by gaz chromatography at Obukhov Institute of Atmospheric Physics.

In spruce forest (Kyiuy site) $CH_4$ concentration is found to vary from 1 to 2 ppm in top-soil (0.1-0.2m) and gradually decrease to 0.3-0.5 ppm down the profile. In larch forest (Sullalr site), significantly higher interannual variability was observed. In dry year (2022) the $CH_4$ distribution resembled that of Kyiuy site, but in wetter years the $CH_4$ concentration in top-soil increased up to 7-36 ppm, suggesting that saturated top-soil layer reduces methanotrophic potential and blocking $CH_4$ release to the atmosphere.

**ABSTRACT**

Soils in periglacial environments, such as those in western Greenland, store large amounts of organic carbon that have accumulated under persistently cold conditions and reduced biological activity. Kangerlussuaq, located in western Greenland at the head of a fjord adjacent to the Greenland Ice Sheet, constitutes the largest ice-free region in Greenland. This area is of considerable scientific interest due to its complex climatic history, characterized by cooling during the early 20th century followed by pronounced and accelerated warming in recent decades. The present study aims to evaluate soil temperature dynamics across different pedolandscapes in western Greenland. During the 2024 field campaign, three soil temperature monitoring stations were installed in proximity to selected soil profiles. Temperature sensors were deployed using an earth auger at depths of 10, 50, and 130 cm below the soil surface. Each sensor was programmed to record temperature at six-hour intervals, resulting in four measurements per day at each depth and enabling continuous long-term monitoring. Temperature data collected between summer 2024 and summer 2025 were retrieved during the subsequent field campaign, yielding a complete annual record. Monthly mean soil temperatures were calculated for each depth. In addition, several thermal indicators were derived, with adaptations to account for the temporal resolution of the measurements: Thawing Days, Freezing Days, Isothermal Days, Freeze–Thaw Days, Thawing Degree Days (TDD), and Freezing Degree Days (FDD). The results reveal pronounced spatial heterogeneity in active-layer thermal regimes over short distances, likely reflecting variations in vegetation cover, soil moisture, and surface energy balance. All monitored profiles exhibited at least one full month with mean temperatures above 0.5 °C, indicating sustained thawing conditions, while all soil layers also experienced at least one complete month with temperatures below −0.5 °C, corresponding to fully frozen conditions. A strong vertical thermal contrast was observed, with high thermal amplitudes in surface layers, contrasting with colder and more buffered subsurface layers characterized by a high frequency of isothermal days, particularly at 30 cm depth. These thermal patterns suggest a bidirectional control of soil temperature on organic matter decomposition along the soil profile, with surface layers responding rapidly to seasonal forcing and deeper layers exhibiting delayed and dampened thermal responses. Overall, thermal monitoring revealed marked seasonal and vertical variability in soil temperature regimes. While surface layers underwent large annual temperature amplitudes, including extended thawed periods during summer and prolonged freezing during winter, subsurface layers displayed more stable thermal conditions, with numerous isothermal days and site-specific differences in thawing and freezing dynamics.

**ABSTRACT**

Freezing-thawing cycles significantly affect the dynamics of soil pore space structure, both directly and through indirect processes. Previous studies have reported varying observations and interpretations regarding the qualitative and quantitative changes in soil structure induced by these cycles. In this study, we conducted freeze-thaw experiments on three different disturbed soil samples. The samples were imaged with an X-ray scanner in their original state and after 1, 5, 10, and 20 freeze-thaw cycles. To process the obtained data, we employed two novel but essential methods:

(1) a custom-built image registration technique to establish identical 3D regions of interest within the scans, and (2) a set of soil structural descriptors with high information content, incorporating both morphological and topological information—correlation functions, pore-network statistics, Euler numbers, and connectivity.

(2) Registration and careful consideration of individual grains within the soil structure enabled robust segmentation of grayscale images into solids and pores.

Unlike most previous studies, we did not observe a steady or nearly monotonic change in structural metrics. Instead, we detected a type of chaotic behavior of these metrics between the freeze-thaw cycles. Using vector descriptors, we demonstrated that the experimental data can be interpreted as hypothetical oscillatory changes within soil structure. This finding leads us to hypothesize that disturbed soils—and possibly natural soils after multiple cycles—undergo periodic structural dynamics. The novel idea behind this hypothesis is simple: as at some point the same temperature impact will not produce the same effect, the structure disturbance will stagnate. From the original state, soils exhibited the strongest structural degradation due to freeze-thaw cycles, whereas in subsequent cycles the dynamics involved both dispersing and aggregating processes, as observed in the X-ray tomography images. We conclude by discussing the necessary future research to confirm or refute this hypothesis and emphasize why soil structure in such experiments should be described using a novel class of vector metrics with high information content, which also subsume most classical soil structural metrics.

## ABSTRACT

Permafrost warming due to rising global temperatures has the potential to alter carbon (C) cycling in high-mountain environments, yet alpine permafrost regions remain poorly studied compared to Arctic systems. In particular, coarse blockfields on alpine summits (>2900 m a.s.l.), often vegetation-free and traditionally assumed to be devoid of soil organic carbon (SOC), may conceal previously unrecognized carbon stocks. To address this gap, we investigated SOC occurrence, stocks, age, and composition in alpine blockfields across the Swiss and Italian Alps.

On nine mountain tops (2900–3350 m a.s.l.) within the periglacial zone (with the addition of a low-elevation fossil Pleistocene blockstream at ca. 1200 m a.s.l.), we removed a layer up to more than one meter thick of coarse blocks and described 18 soil profiles hidden below. Some of the sites were completely barren, while in others a few plants grew between the stones or in the central parts of sorted patterned ground morphologies. Weakly decomposed plant fragments of aeolian origin were found at the base of the stone layer in six soil profiles. Below, the observed soils showed dark brown to black A horizons with thickness between few and 62 cm, overlying Bw, Bs or C horizons. The texture was usually sandy loamy to loamy sand, with very few stones, and the pH was usually acidic to strongly acidic. In different sites, soils could be classified as Akroskeletic Cambic Umbrisols, Dystric Akroskeletic Cambisols, Akroskeletic Regosols, and one as an Akroskeletic Entic Podzol.

In the A horizons, the C content was between ca. 3.2 and 37.2 g $kg^{-1}$, usually with C/N ratios between 8 and 15, indicating well-decomposed organic matter. The C stocks were significant, considering the barren landscape of blockfields, and they were between 0.8 and 10 kg C $m^{-2}$. The soils showing the strongest weathering degree like the Umbrisols, Cambisols and the Podzol (likely predating the Holocene) had the largest C stock.

Radiocarbon dating revealed that plant fragments were mostly recent, while the humic materials in the dark A horizons ranged between ~4,000 years near the surface to ~12,900 years at depth, with some extreme values (17,000 and 22,000 years) in a Monte Rosa massif blockfield. Between 65% than 90% of organic carbon was stored in a stable mineral-associated organic matter pool, highly decomposed and dominated by lipids, waxes, cellulose, and hemicellulose. Thin section observations under optical microscope and SEM-EDS images verify the strong decomposition degree of such humified material. Although the aeolian origin of the soil was well visible in one site (Venerocolo summit, Adamello massif), the organic matter composition did not allow us to distinguish an aeolian pool, and one originated from ancient alpine tundra vegetation that developed during warmer climatic phases. Together, these findings demonstrate that alpine blockfields and periglacial features can host substantial, millennia-old, and largely stable SOC pools, preserved for long times by cold soil temperatures and metal-organic stabilization. These "hidden" carbon reservoirs likely formed through a combination of Holocene vegetation inputs and atmospheric deposition and may become vulnerable to mobilization under future climatic warming, with implications for alpine carbon–climate feedbacks.

# Soil organic carbon stock assessment in cryoturbated turf/grass mounds in Kobresia Medows, Qinghai-Tibetan Plateau)

**ABSTRACT**

Soil organic carbon (SOC) is a critical component of terrestrial ecosystems, serving as a key indicator of soil health and ecosystem function. Despite growing research on SOC estimation at regional, national, and global scales, accurately quantifying SOC in the Arctic and alpine regions remains challenging due to periglacial features. These features include sorted and nonsorted circles, earth hummocks, turf mounds and ice wedge polygons and other features formed due to cryoturbation. To overcome the high special heterogeneity caused by these features, the pedologists and geocryologists have developed the approach of applying the pedon concept to sample the soils across those periglacial features in the past decades. To take an example of the nonsorted circles (frost boils), the pedon is defined from the center of the circle to the center of the depressed area between the circles, as called “inter-circles”. The dimension of the pedon can be from 1 m to 3.5m wide and depth to 3m or as limited by paralithic or bedrock contact, or massive ice. Thus, for the turf hummocks dominated by Kobresia, the pedon is defined from the center of the hummocks to the centers of the depressions in between the hummocks. The soil horizons or zones on the exposed profile are delineated and the percentage of each zone of the whole profile is calculated. The C density of the whole profile is calculated by the summation of the percentage of the C storage of each zone expressed as kg/m$^3$.

**ABSTRACT**

The mattic layer (ML), a dense root-soil matrix formed predominantly by Kobresia sedges, constitutes a keystone pedogenic feature governing ecosystem functioning across 2.5 million km² of the Qinghai-Tibetan Plateau. However, the ML rupture as widespread structural failures now threaten this vital ecological barrier, initiating cascading degradation with far-reaching implications for carbon cycling, hydrology, and biodiversity. This review provides the first comprehensive synthesis of ML ruptures through an integrated framework from formation, distribution, and consequences, to monitoring. Contemporary ruptures manifest as five distinct morphotypes driven by synergistic anthropogenic and natural factors. Anthropogenic drivers include overgrazing exceeding carrying capacity by 50-165%, infrastructure development, and resource extraction. Natural drivers encompass climate warming at 0.31-0.39°C per decade, permafrost degradation, intensified freeze-thaw cycles, and biotic disturbances. These factors generate self-reinforcing feedback loops that push systems beyond recovery thresholds. Consequences cascade from immediate soil degradation through hydrological disruption to transformation of carbon sinks into sources, and social-economic impacts at both the local and global scale. The ML rupture represents more than just regional degradation; it fundamentally alters carbon cycling and climate regulation with impacts extending from pastoral livelihoods to global systems. The monitoring of ML rupture has evolved from conventional field investigations to integrated remote sensing and in-situ sensor networks, enabling unprecedented spatiotemporal resolution for tracking ML rupture dynamics. Despite extensive research on individual components, critical knowledge gaps persist regarding formation-rupture linkages, threshold dynamics, and the synergistic interplay of multiple drivers. This synthesis establishes a scientific foundation for understanding ML responses to global change and developing targeted conservation strategies for these irreplaceable alpine ecosystems facing unprecedented environmental pressures.

# Study on the coupling relationship between agricultural water and soil resources carrying capacity and grain production capacity in typical black soil regions of Northeast China

**Wang Sidi[1*], Pei Jiubo[1]**

*[1] College of Land and Environment, Key Laboratory of Arable Land Conservation in Northeast China, Ministry of Agriculture and Rural Affairs; National Engineering Research Center for Efficient Utilization of Soil and Fertilizer Resources, National Development and Reform Commission, Shenyang Agricultural University, Shenyang, China*

**ABSTRACT**

The Northeast Typical Black Soil Region (NETBSR), a vital grain production base in China, has long played a critical role in safeguarding national food security. However, intensive agricultural practices, climate change, and unsustainable resource utilization have collectively challenged the carrying capacity of its agricultural water-land resources, threatening regional food production sustainability. This study employs the DPSIR (Driving Forces-Pressure-State-Impact-Response) framework to establish a comprehensive evaluation system for agricultural water-land resource carrying capacity (AWRCC). Using entropy-weighted TOPSIS modeling, we systematically assessed the spatiotemporal evolution of AWRCC in NETBSR from 2002 to 2022. The Miami model and spatial analysis techniques were integrated to estimate grain production potential, quantify spatial coupling relationships between AWRCC and production capacity, and analyze correlations with actual yields. Key findings include:

1. AWRCC exhibited marked spatiotemporal dynamics, increasing from 0.38 to 0.64 during 2002–2022. A slight decline occurred during 2002–2007 due to overexploitation of arable land, followed by accelerated growth (2008–2015) driven by black soil conservation policies and water-saving agriculture. Post-2016, growth stabilized, yet regional disparities persisted, with the Songnen Plain consistently outperforming other subregions.
2. Grain production capacity rose from 5,800 to 7,300 kg/ha, demonstrating pronounced spatial heterogeneity. High-yield zones (7,500 kg/ha in Songnen Plain; 7,200 kg/ha in Sanjiang Plain) contrasted with low-yield areas (6,000–6,200 kg/ha in Heihe and Jixi), influenced by policy shifts, climatic variability, and land-use patterns.
3. While a significant positive correlation is observed between agricultural water and soil resource carrying capacity and grain production capacity at the overall level ($r = 0.67$), temporal and spatial fluctuations indicate phases of coupling imbalance in specific years and regions. This relationship was especially strong in the Songnen Plain region ($r > 0.75$). In contrast, the correlation with actual grain output was weaker ($r = 0.42$), suggesting that grain production is influenced not only by resource endowment but also by external factors such as market demand, policy shifts, and cropping structure transformation.
4. Precipitation, primary output value and the proportion of high water-consuming crops are the main obstacles to the carrying capacity of regional agricultural water and soil resources. Notable differences in barrier structures were observed across regions with varying levels of grain production potential. By identifying critical constraints and proposing differentiated management strategies, this study provides theoretical support and practical insights for enhancing agricultural sustainability and grain productivity in the black soil region of Northeast China.

## ABSTRACT

The black soils in Northeast China are the main production area of grain crops in China and are of great significance to ensuring national food security. However, the black soils in this region have been degraded due to long-term high-intensity utilization and climate change. Soil "hardening" is an important factor of declining arable land quality in this region. Although many studies have increasingly paid attention to the degradation of soil organic matter and nutrients in black soils, the systematic understanding of the key factor of soil "hardening" and their spatial distribution pattern are still relatively insufficient in the black soils in Northeast China. At the same time, the lacks of measured bulk density data in the existing soil database have led to be difficulty in assessment the accuracy of large-scale soil "hardening". Although the random forest model is widely used in soil property prediction, its application for spatial prediction and mapping in soil bulk density is still relatively scarce. Therefore, it is of great practical significance to clarify the spatial distribution pattern and driving factors of soil bulk density and compactness of typical black soil in Northeast China, and to explore the establishment of soil bulk density transfer function. So this study takes the black soil in Songnen Plain as the research object, combines field surface soil survey with soil profile survey, and comprehensively uses geographic detectors, random forests and other methods to explore the spatial distribution characteristics of soil bulk density and compactness in the Songnen Plain, and explore the main influencing factors of key indicators of soil "hardening", and further construct the transfer function between soil bulk density and other soil properties, in order to provide a scientific basis for the rapid diagnosis of the degree of "hardening" of black soil in the region. The main research results were as follows:

(1) The variation characteristics of soil bulk density and compaction in the surface and subsurface layers of different soil types were different. Black soil, meadow soil and dark brown earth showed different variation patterns with depth. The variation trend of soil bulk density of black soil with depth was relatively stable, and the power function model had a better fitting effect ($R^2$=0.63); the variation range of soil bulk density of meadow soil with soil depth was relatively large; the soil compaction of dark brown earth increased significantly with the increase of profile depth, and the power function model had the best fitting effect ($R^2$=0.89).

(2) The spatial distribution of soil bulk density and compaction in the black soil region of the Songnen Plain was characterized by regional variability. Prediction mapping showed that soil bulk density exhibited an overall increasing trend from north to south, with higher subsurface bulk density observed in the southern and central areas (e.g., Songyuan and Siping). In contrast, surface and subsurface soil compaction was found to be relatively higher in the northern and northwestern parts of the region (e.g., Hulunbuir and Heihe), indicating a certain degree of spatial divergence between the two. However, spatial consistency between bulk density and compaction was observed in areas such as eastern Harbin and southeastern Suihua.

(3) The spatial variation of soil bulk density and compaction was influenced by multiple factors, including soil organic matter content, and interactions among these factors were observed. Soil organic matter content was found to have a strong explanatory power for both surface and subsurface bulk density. The interaction between soil organic matter and mean annual temperature provided the highest explanatory power for surface bulk density ($q$=0.51). In terms of soil compaction, water content exhibited strong combined effects with other variables, with the interaction between water content and mean annual temperature showing the strongest explanatory power ($q$=0.53).

(4) Support vector machine, binomial and generalized linear model methods are effective in constructing bulk density transfer functions based on soil organic matter and compaction. Among these, the binomial model and support vector machine demonstrated higher accuracy and stronger explanatory power when fitting the relationships between organic matter and bulk density ($R^2$=0.43), as well as compaction and bulk density ($R^2$=0.56). In addition, the transfer function constructed based on soil compaction performed better in the subsurface layer ($R^2$=0.56).

The results indicated that the spatial distribution of soil bulk density and compaction in the black soil region of the Songnen Plain was characterized by regional differences. These differences were influenced by both natural and anthropogenic factors, among which soil organic matter content was identified as the primary influencing factor, and interactions with climate and topography were observed. The support vector machine and binomial regression models were found to perform better in predicting soil bulk density, especially when the transfer function was constructed based on soil compaction in the subsurface layer. This demonstrated the potential of compaction-based models for rapid diagnosis of soil "hardening" in black soil regions.

# Integrating Remote Sensing and Soil Drainage Mapping to Predict Salinization Risk

**G. Gowera[1*], P. Sorenson[2], and A. Bedard-Haughn[3]**

[1,2,3] *(Soil Science Department, University of Saskatchewan, Saskatoon, Canada)*

*bkm374@usask.ca

**ABSTRACT**

Salinization is a major threat to agricultural sustainability, particularly in semi-arid regions where salt accumulation degrades soil quality and limits crop productivity. Existing salinization risk maps often rely on outdated, polygon-based datasets that oversimplify spatial variability and fail to capture emerging risk zones. To address this gap, this study developed a high-resolution, raster-based salinization risk tool using remote sensing and terrain analysis. A key innovation of the approach is the integration of a newly developed drainage classification model as an input for assessing salinization risk. Using remotely sensed imagery and terrain variables derived from a 5-m digital elevation model (DEM), a Support Vector Machine (SVM) model was trained to classify soil drainage, achieving a Kappa coefficient of 0.64, with sensitivity values of 0.82 for well-drained, 0.87 for poorly drained, and 0.50 for very poorly drained areas. The resulting drainage layer, along with four other key salinization drivers (aridity, surface cover, current salinity, slope) were weighted using Grey Relational Analysis and ranked based on their relative influence on salinization. These ranked inputs were then combined to produce a spatially explicit salinization risk map, enabling more detailed and actionable identification of at-risk zones at the field scale.

# Geostatistical fusion of field and remote sensing data for assessing soil salinity in southern region of Morocco

Issam.Barra@um6p.ma

**ABSTRACT**

Soil salinization is the process of accumulation of water-soluble salts within the upper part of soil profile (particularly A and B horizons). Salinization originates from different sources and is one of major worldwide soil threat which rarely comes alone. Therefore, quantifying and spatial modelling of indicators of salinization is crucial to manage and mitigate the soil salinization process. The use of remote sensing in mapping and assessment of soil salinization represents the possibility of achieving ever greater spatial resolution. Particularly in conditions where it is difficult or too much expensive field measurements or collecting soil samples. One of this case is presented in this study in a southern region of Morocco. 490 samples were taken from these regions from 0 to 20cm depths The sampling method was designed to capture the maximum variability across all the study areas while ensuring the homogeneity of samples in each sub-region. 490 samples were taken from these regions from 0 to 20cm depths.

A crucial problem to be solved to use spatial data of different nature and characteristics such as field and remote sensing data is the support of measurement, which is very different between the types of data. Therefore, to solve this issue and derive the maximum information, it is necessary to apply appropriate techniques of spatial statistics by defining a spatial statistical model. In this study, a multivariate geostatistical approach is proposed that can fuse data of different types, including soil sample satellite data, to model and map soil electrical conductivity considering the various supports and their impacts on prediction. Remote sensing data consists in pixels which are considered as the average reflectance of light from a limited support. Therefore, decomposing the original support into a set of finer supports was necessary to combine field and remote sensing data.

# Study on Soil Organic Matter Inversion of Different Textural Soils in the Northeast Black Soil Region Based on Hyperspectral Remote Sensing

**Ma Minghui[1*], Gao LL[2], Cheng Li[1],Xicun Zhu[1],Sui Yueyu[3] and Zhao Yuguo[2]**

*[1] College of Resources and Environment, Shandong Agricultural University, Taian 271018, China*

*[2] State Key Laboratory of Soil and Sustainable Agriculture, Institute of Soil Science, Chinese Academy of Sciences, Nanjing 211135 (China)*

*[3] State Key Laboratory of Black Soils Conservation and Utilization, Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun 130102, China*

*1503756179@qq.com

**ABSTRACT**

Considering that the ability of hyperspectral estimation of soil organic matter is influenced by soil texture, grouping soil samples according to texture is a strategy to improve prediction accuracy. This study takes Heilongjiang, Jilin, Liaoning provinces, as well as Hulunbeir City, Xing'an Prefecture, Tongliao City, and Chifeng City in Inner Mongolia as the research areas, with 347 soil samples as the research objects. Based on the United States Department of Agriculture (USDA) soil texture classification standards, the samples are divided into four groups: sandy soil, loamy soil, loamy clay, and clay, and a control group without distinguishing soil texture is set up. Firstly, the spectral reflectance characteristics of total samples and four groups of samples with different textures are systematically analyzed. Secondly, after comparing various spectral preprocessing methods, the Multiple Scatter Correction + Savitzky-Golay (MSC+SG) method is selected as the optimal preprocessing scheme based on the Pearson correlation coefficient. Then, the Competitive Adaptive Reweighted Sampling (CARS) and Successive Projections Algorithm (SPA) are used to screen characteristic bands, and the similarities and differences of characteristic bands among different soil samples are analyzed. Subsequently, Random Forest (RF) and Partial Least Squares Regression (PLSR) are employed to construct inversion models, and the accuracy of the models is verified and evaluated. Finally, based on the spectral reflectance characteristics and characteristic bands of different soil samples, remote sensing images are used for comparative analysis, and organic matter distribution maps are drawn. The main research results are as follows: (1) When soil texture is not distinguished, the PLSR constructed by MSC+SG combined with CARS-SPA has the best inversion effect on hyperspectral organic matter in soil, with a coefficient of determination ($R^2$) of 0.67, a root mean square error (RMSE) of 11.45, and a relative analysis error (RPD) of 1.67. (2) When soil texture is distinguished, the optimal inversion model for all four groups of soil is MSC+SG-PLSR, with $R^2$=0.99 and RMSE=1.21 for the sandy soil group, $R^2$=0.52, RMSE=12.26, and RPD=1.47 for the loamy soil group, $R^2$=0.85, RMSE=6.07, and RPD=2.69 for the loamy clay group, and $R^2$=0.66, RMSE=9.10 for the clay group. The inversion accuracy is significantly improved compared to when soil texture is not distinguished. This indicates that soil texture in the black soil region of Northeast China has a significant impact on the accuracy of hyperspectral inversion of organic matter. This study provides technical support for monitoring soil organic matte content in the black soil region of Northeast China.

# An airborne platform for enhanced soil characterization

**R. le Roux**[1*]

[1] *Department of Technology, Faculty of Military Science, Stellenbosch University, South Africa*

*rikusr@sun.ac.za

**ABSTRACT**

Advances in remote sensing have transformed the way soils are monitored, mapped, and managed for agricultural productivity. Soil properties such as texture, moisture, organic matter, and nutrient status vary across landscapes, influencing crop performance and resource-use efficiency. Accurate and spatially resolved measurements of these properties are therefore essential for precision agriculture, where site-specific management decisions depend on detailed knowledge of soil variability.

This work introduces the development and planned application of an airborne platform aimed at improving soil characterisation for precision agricultural use. The system integrates multispectral imaging, radiometric measurements, and geospatial positioning to enable the rapid collection of surface and environmental data across extensive and often inaccessible agricultural landscapes. By capturing reflectance patterns and associated environmental signatures, the platform is designed to facilitate the estimation of key soil parameters relevant to crop health, resource-use efficiency, and land-management planning.

The presentation will outline the system architecture, survey design, and planned analytical workflows for processing airborne data and generating spatially detailed soil maps. These workflows are intended to reveal patterns in soil condition, support the delineation of management zones, and guide targeted interventions such as variable-rate fertilisation and irrigation scheduling. The platform's flexible and repeatable deployment is expected to enable ongoing monitoring of temporal changes in soil status and to strengthen decision-making in precision agriculture. Overall, the approach has strong potential to enhance agricultural monitoring, improve resource-use efficiency, and support sustainable land management and long-term soil health.

*[1] State Key Laboratory of Efficient Utilization of Arid and Semi-arid Arable Land in Northern China, Institute of Agricultural Resources and Regional Planning, Chinese Academy of Agricultural Sciences, Beijing 100081, China*

*lumiao@caas.cn

**ABSTRACT**

Soil salinization is one of the major soil degradations that threats agricultural production and food security, particularly in arid and semi-arid regions. Remote sensing is an important tool for monitoring soil salinity information on a large scale. Although remote sensing allows for the soil salinity mapping by analyzing the spectral responses of soil and vegetation, a common limitation is the oversight of field management practices, which are known to significantly influence soil moisture dynamics and salinity accumulation. Compared to healthy cropland, saline cropland requires distinct field management practices, such as higher salt-tolerant crops and higher irrigation demands. Consequently, field management information represents a potent indicator for soil salinity mapping in cropland, yet it remains overlooked in related researches.

This study addresses this gap by integrating novel agronomic features—crop planting structure and irrigation indicator—into salinity prediction models. Crop planting structure was a quantitative representation of crop classification results using target encoding. The irrigation indicator was derived from the Temperature Vegetation Dryness Index (TVDI) to capture seasonal soil moisture variations associated with irrigation during the growing season. Lastly, we established a predictive model of soil salinity content using Extreme Gradient Boosting (XGBoost). The variables were grouped into several combinations to explore the effects of different feature types. We chose a typical region with frequent agricultural activities in the arid and semi-arid climate zone in northwestern China.

Our results demonstrate that incorporating these features significantly improves model performance compared to conventional models using only environmental and spectral variables. The coefficient of determination ($R^2$) increased by 0.11 reaching 0.74. Notably, crop planting structure emerged as the most influential predictor, underscoring the value of field management information in cropland salinity mapping. Future research will explore advanced spatial representations of management practices, such as the distribution of irrigation infrastructure and continuous cropping years, to further enhance predictive reliability in soil salinity mapping.

## ABSTRACT

Comprehending fine-scale soil variability is crucial for enhancing vineyard management within precision agriculture, because spatial heterogeneity in soil properties and erosion dynamics directly influences vine water availability, nutrient cycling, and the long-term soil functionality. Soil contamination is a multifaceted process that jeopardizes ecosystem services and agricultural sustainability, emphasizing the need for rapid, spatially comprehensive diagnostic methods such as proximal or remote radiometric sensing. This study investigated the potential of unmanned aerial vehicle (UAV)–mounted gamma-ray spectrometry (GRS) to map soil texture, characterize primordial radionuclide activities ($^{40}$K, $^{238}$U, $^{232}$Th), and trace sediment-erosion processes across a commercial vineyard. High-resolution radiometric measurements were acquired using a lightweight scintillation detector flown at low altitude (≤5 m), enabling detection of natural gamma emissions associated with mineralogical composition and the redistribution of surface materials. Soil gamma radiation frequently shows robust correlations with texture, as radionuclides are structurally incorporated into specific minerals (e.g., K in illite and mica), adsorbed onto the soil's cation-exchange complex, or immobilized within Fe–Mn oxides and other heavy mineral fractions. These relationships allowed radiometric variations to serve as indirect indicators of textural gradients. Additionally, spatial deviations in radionuclide activities acted as tracers of soil erosion, reflecting the selective removal and deposition of fine particles along the landscape. After applying corrections for flight altitude, soil moisture, and detector response, spectral analysis was conducted to derive radionuclide enrichment patterns linked to soil movement, textural gradients, and potential contamination pathways. Ground-truth soil samples were collected for laboratory analysis of texture, radionuclide concentrations, and organic and inorganic soil constituents. Both the in-situ measurements and laboratory datasets were interpolated using Geographic Information Systems (GIS)–based Inverse Distance Weighting (IDW) to generate continuous spatial surfaces for comparison with UAV-derived radiometric maps. These interpolated layers were used to refine predictive modelling frameworks and improve interpretation of erosion signatures, radionuclide redistribution, and contamination trends. The integration of UAV data with in-situ observations, laboratory assays, and modelling frameworks enhanced the capacity to map degradation patterns and assess recovery trajectories within the vineyard landscape. The resulting spatial products revealed soil zones shaped by parent-material variability, slope-controlled sediment transport, and management-related disturbances. Overall, the study demonstrated the potential of UAV-borne gamma-ray spectrometry as a rapid, non-destructive tool to support targeted soil amendments, erosion-mitigation strategies, and sustainable precision agriculture in viticultural systems.

# Soil Reflectance Composite and Terrain Attributes for Digital Soil Mapping in a Mediterranean Cropland District

**ABSTRACT**

Accurate soil maps are essential for soil protection, policy implementation, and digital agriculture. However, traditional soil maps often lack the detail required for local applications, while farm-scale surveys are often not economically sustainable.

This study was carried out within Rieti plain, an important agricultural area of about 40 km2 in central Italy (Zanini et al., 2024). Legacy soil data and digital soil mapping (DSM) were used to produce accurate, low-cost maps of key soil properties, namely clay, sand, total lime (CaCO3), organic carbon (SOC), total nitrogen (TN) and cation exchange capacity (CEC). The DSM procedure involved Multivariate Stepwise Regression Kriging that uses terrain attributes and bare soil reflectance composite (SRC) from Sentinel-2 multi-temporal images. SRC was obtained using the Soil Composite Mapping Processor (SCMaP), an automated methodology for extracting the reflectance of bare soil pixels of each image . The SRC map was then created by calculating the average of the extracted bare soil pixels, between 19 and 391 dates over a five-year period (2018-2022). The SRC map of all of Europe is now available as e.g. a WMS service at https://geoservice.dlr.de/eoc/land/wms (Heiden et al., 2025).

The Sentinel-2 bands of SRC showed strong correlations with topsoil features (A horizon), making them highly suitable explanatory variables for regression kriging. In particular, the SWIR bands (b11 and b12) were key in predicting clay, sand, and CEC maps. The regression models were highly accurate for clay, sand, SOC, and CEC ($R^2 > 0.90$), but showed lower accuracy for CaCO3 ($R^2 = 0.67$). Similar results were obtained when predicting subsoil (B horizon) clay and sand content, probably for the cross-correlation between topsoil and subsoil features.

Additionally, a supervised classification approach was applied to predict Soil Typological Units (STUs) based on the mapped soil attributes and STU classification in the described profiles. This methodology demonstrates the potential of SRC and regression kriging for producing detailed soil property maps to support precision agriculture and sustainable land management.

## ABSTRACT

Digital soil mapping (DSM) enables spatially and temporally explicit prediction of soil attributes relevant to agricultural sustainability and carbon accounting. This study developed an integrated workflow to predict soil organic carbon (SOC) stock from 2000–2025 using a SCORPAN-based covariate framework and machine learning. A harmonized soil database of >12,000 data point (0–30 cm) from Chile supported model calibration. Static covariates included terrain attributes (GEDTM30), long-term climate (WorldClim, aridity index), soil class probabilities (SoilGrids), geomorphology, oblique coordinates, and distance to water bodies. Dynamic covariates were derived annually from Landsat Collection 2, including reflectance bands, vegetation indices (NDVI, NDWI, NDSI), spectral unmixing fractions, and temporal trend metrics based on Sen's slope. Additional dynamics included annual ERA5-Land climate variables, MODIS LST (day/night), and land-use intensity. All covariates were resampled at 30 m resolution. Localized models were developed using LightGBM, optimized via halving grid search cross-validation, and trained separately for OM and BD using region-specific data weighted by inverse distance to the geomorphological strata covering the study area. Model performance was evaluated using independent train–test splits and $R^2$, RMSE, MAPE, RPIQ, and Lin's concordance (CCC). OM prediction achieved $R^2 = 0.70$, RMSE = 2.79%, CCC = 0.82, and RPIQ = 4.49. BD predictions showed stronger performance ($R^2 = 0.83$, RMSE = 0.09 g $cm^{-3}$, CCC = 0.91, RPIQ = 7.36). Optimized models were applied to generate space-time annual predictions from 2000 to 2025. SOC stock (t C $ha^{-1}$) was computed from SOC (OM*0.58) and BD predictions, ensuring equivalent mass-based comparison across time. Temporal analysis of SOC stock revealed clear declining trends across the area. Mean SOC decreased at −0.66 t C $ha^{-1}$ $yr^{-1}$, the 95th percentile at −0.73 t C $ha^{-1}$ $yr^{-1}$, and the median at −0.49 t C $ha^{-1}$ $yr^{-1}$. Even the lower bound (5th percentile) showed a modest decline of −0.03 t C $ha^{-1}$ $yr^{-1}$. These consistent negative slopes indicate widespread SOC losses over the 25-year period, with higher-SOC areas presenting the strongest declines. The resulting maps show pronounced spatial and temporal variability in SOC stocks, driven by land management and environmental gradients. Space-time maps can be explored via the Soil Explorer web interface (https://geospatial-425519.projects.earthengine.app/view/soil-explorer). The proposed SCORPAN–ML workflow provides a robust, scalable framework for high-resolution DSM and supports precision agriculture, carbon monitoring, and sustainable land-use planning.

## ABSTRACT

Soil salinization is a key factor impeding agricultural sustainable development; thus, accurately acquiring large-scale time-series soil salinity information is of great significance for ensuring national food security. As a pivotal element of the spaceborne Global Navigation Satellite System Reflectometry (GNSS-R) mission, Cyclone Global Navigation Satellite System (CYGNSS), with its advantages of high spatio-temporal resolution and strong penetration capability, can extract soil salinity information mechanistically without relying on in-situ samples. However, complex surface effects and the confounding influence of moisture on the soil dielectric constant constitute the pivotal scientific challenges limiting high-precision CYGNSS soil salinity retrieval. Based on CYGNSS data, this study proposed a novel soil salinity retrieval model (PRD) through two primary steps: First, a combined surface attenuation correction method rooted in microwave radiation principles was established. The resulting corrected surface reflectivity demonstrated good consistency with soil moisture data from Soil Moisture Active Passive (SMAP) (R=0.84). Second, this surface reflectivity was fused with an improved soil dielectric constant model to uncover the bridging mechanism of soil dielectric properties in soil salinity retrieval. The PRD model's accuracy was subsequently validated using in-situ soil salinity data and compared to the CYGNSS empirical correction (ERD) model. Validation confirmed the PRD model's superior performance, achieving the coefficient of determination ($R^2$) of 0.83, the root mean square error (RMSE) of 0.53‰, and the ratio of performance to deviation (RPD) of 2.33. The spatio-temporal dynamics of soil salinity in the Yellow River Delta in 2023, derived from the PRD model, revealed a climate-driven seasonal cycle: Salinity peaked at 4.75‰ in May (accumulation phase) and reached its minimum at 2.35‰ in July (leaching phase). High-salinity zones were concurrently observed to be structurally fixed along the coastline and inland depressions. In essence, these findings establish the PRD model's feasibility and capability as an accurate, physics-informed framework for advancing continuous, large-scale soil salinization monitoring using GNSS-R technology.

## ABSTRACT

Traditional soil heavy metal source apportionment relies on point-based chemical analysis, which often overlooks the critical influence of spatially continuous landscape patterns on pollution distribution. This study proposes an innovative approach, developing an explainable geospatial AI framework to directly infer the likelihood of exogenous cadmium (Cd) contamination from landscape features within remote sensing (RS) imagery.

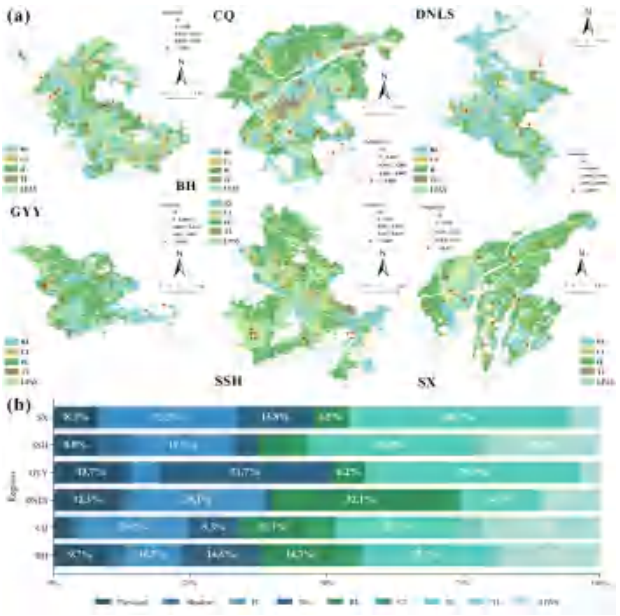

Fig. Occlusion sensitivity analysis (OSA) unveils critical scenarios driving Cd pollution prediction. (a) Spatial distribution of high-sensitivity patches overlaid on urban land use types. (b) Quantitative contribution of different land use types to positive sensitivity, unequivocally identifying industrial land (IL) as the primary driver across regions. RL—residential land; CL—commercial land; IL—industrial land; TL—transportation land; LPAS—land for public administration and service; FL—forest land; WA—water area.

Our methodology establishes a novel link between extensive ground-truth data (14,058 soil samples) and high-resolution RS imagery in Dongguan, China. We designed a lightweight convolutional neural network, SI-LICNet, specifically architected to preserve large-scale spatial information essential for identifying landscape-level pollution indicators. Crucially, to deconstruct the model's decision-making process, we employed Occlusion Sensitivity Analysis (OSA) to quantitatively identify and visualize the critical scenarios most influential in predicting Cd pollution.

The SI-LICNet models demonstrated robust predictive performance, achieving regional Area Under the Curve (AUC) values ranging from 0.747 to 0.905 and recall rates consistently exceeding 70%, confirming their efficacy in detecting pollution hotspots. The OSA results provided direct, interpretable evidence: industrial land was unequivocally identified as the primary landscape type driving high-Cd predictions across functionally diverse urban regions. For instance, in regions like Binhai (BH) and Gongyeyuan (GYY), industrial zones and adjacent transportation networks showed the highest sensitivity. Interestingly, even misclassified "false positive" samples were found to represent areas with high contamination risk, as their landscape features closely mirrored those of verifiably polluted sites.

This work transforms deep learning from a "black-box" classifier into an interpretable tool for environmental forensics. By successfully identifying key pollution-related scenarios from satellite imagery, our approach offers a scalable, cost-effective, and scientifically rigorous methodology for dynamic soil pollution monitoring and targeted environmental management.

# Advancing Corn Yield Prediction through Cross-Scale Integration Approaches

**ABSTRACT**

Predicting crop yields consistently from field to regional scales is still a major limitation in precision agriculture, especially due to the difficulty of linking in situ observations with remotely sensed data. In this work, we introduce a new multi-scale modeling approach that combines ground-truth measurements, UAV imagery, and satellite products to improve the reliability of corn yield estimates. The study was carried out at a farm in Ontario, Canada, using Sentinel-2 imagery together with fine-resolution UAV data acquired over the 2019 and 2020 growing seasons. Two yield estimation frameworks were implemented and evaluated: a traditional satellite-only model and a novel multi-scale upscaling scheme that explicitly links information across spatial resolutions. The upscaling framework outperformed the conventional approach, increasing the correlation coefficient from 0.82 to 0.88. More importantly, the proposed upscaling approach markedly lowered prediction uncertainty, reducing the proportion of high-uncertainty areas (>1%) from 43.3% to 20.4%. Examination of spectral predictors highlighted clear scale-specific responses, as vegetation indices including the canopy chlorophyll content index (CCCI), chlorophyll index (CIgreen), and green normalized difference vegetation index (GNDVI), exhibited different levels of influence depending on spatial resolution. In addition, the framework enabled explicit tracking of uncertainty transfer across scales, addressing a key limitation of existing precision agriculture methodologies. The results confirm that structured integration of observations from multiple spatial scales can simultaneously enhance yield prediction accuracy and minimize uncertainty, with direct relevance for precision agriculture and sustainable crop management practices.

**ABSTRACT**

Sustainable crop production increasingly relies on maximizing nitrogen (N) efficiency while safeguarding yield levels. Nevertheless, the intertwined effects of soil variability, fertilizer management, and plant physiological response complicate the development of accurate, site-specific N recommendations. This research therefore sought to (a) determine how soil characteristics influence crop spectral reactions to N supply, and (b) derive soil-dependent N response models using remote sensing metrics. A comprehensive dataset combining soil attributes, nitrogen application levels (zero, regular, and luxury rates), and Sentinel-2–based spectral metrics was collected from a maize field in Ontario, Canada. Structural equation modeling and random forest techniques were applied to derive soil-dependent N response relationships and to assess predictive performance under three progressively integrated modeling scenarios. Soil cation exchange capacity (CEC) and organic matter (OM) emerged as key regulators of N responsiveness, with the green normalized difference vegetation index (GNDVI) exhibiting the strongest association with yield ($r = 0.80$) in areas characterized by high CEC. Including soil information increased yield prediction accuracy by 16% relative to models relying solely on remote sensing, while the additional integration of N management variables further decreased prediction error by 21%. Although applying N at luxury rates resulted in a 4.8% yield increase over recommended levels, the magnitude of this gain differed markedly across soil conditions. These findings demonstrate that soil heterogeneity plays a central role in governing crop responses to N inputs, underscoring the limitations of uniform fertilizer recommendations. The proposed framework supports the development of soil-specific N management strategies that can improve yield outcomes while advancing environmental sustainability in heterogeneous agricultural landscapes.

**ABSTRACT**

Mining activity has driven technological and economic development but also generates severe environmental impacts, such as Acid Mine Drainage (AMD). AMD occurs when sulfides react with water, oxygen, and microorganisms, producing acidic solutions that mobilizes potentially toxic elements (PTEs). AMD contaminates soil, as well as surface and groundwater bodies, deteriorating their quality, affecting ecosystem services, and posing risks to human health.

Traditionally, AMD evaluation has relied on single chemical analysis of parameters like pH and electrical conductivity (EC), as well as on the identification of secondary minerals (e.g., jarosite, anhydrite, goethite). However, there is no integrated index based on Geographic Information Systems (GIS), geostatistics, and remote perception (RP) combining these parameters to estimate the impact of AMD on soils.

A mixed RS, geostatistics and GIS approach, offers an efficient and low-cost alternative to identify and spatially model AMD affected edaphic parameters (geochemical and mineralogical). Thus, our research proposes the AMD Soil Impact Index (herein called "IIMSDAM") applicable to any area presenting historical or active mining operations. The developed index parameters are pH, EC, slope, distance to AMD sources (mines and mine tailings), and secondary AMD minerals (Jarosite, goethite, ferrhidrita, anhydrite, gypsum).

The AMD index was applied to the municipalities of Banámichi, Huépac, and San Felipe de Jesús, Sonora, Mexico, a region with a long mining history and potential AMD contamination.

The approach we have adopted allowed AMD affected soil mapping and classification, representing a valuable resource to optimize decision-making in environmental management and mining exploitation. Our study provides a globally replicable tool for the prevention, monitoring, and remediation of mining-degraded soils.

# Multi-view hyperspectral feature can improve soil property retrieval

**Lixia Ma[1*], Yufei Zhou[1,2], Xianzhang Pan[1], and Dongsheng Yu[1]**

[1] *State Key Laboratory of Soil and Sustainable Agriculture, Institute of Soil Science, Chinese Academy of Sciences, Nanjing, China*

[2] *College of Geography and Environment, Shandong Normal University, Jinan, China*

*E-mail Address of Presenting Author: malixia@issas.ac.cn

**ABSTRACT**

Hyperspectral remote sensing has been increasingly used for retrieving soil properties. Most previous studies have relied on reflectance data acquired from a single viewing angle, typically the nadir direction, while the potential benefits of multi-view hyperspectral observations remain insufficiently explored. This study aims to develop an optimal framework for soil property retrieval by incorporating soil bidirectional reflectance distribution function (BRDF) characteristics and to identify the multi-angle hyperspectral features that enhance retrieval accuracy. Soil reflectance was measured at 48 viewing angles for different soil samples. Three feature wavelength selection methods and four modeling algorithms were evaluated to identify the most effective combinations for retrieving soil organic matter content, cation exchange capacity, pH, and sand, silt, and clay contents using hyperspectral data from different viewing angles. Variations in retrieval accuracy and selected feature wavelengths across view angles were further analyzed to determine the key multi-angle spectral features contributing to improved predictions. Finally, these multi-angle spectral features were simulated from nadir reflectance and validated for their effectiveness. The results showed that, for linear models, the combined feature selection strategy using random frog (RFROG) and competitive adaptive reweighted sampling (CARS) outperformed either method alone, with $R^2$ increases of 3.1%–197% and 2.3%–214%, respectively. When nonlinear models were applied, the RFROG–CARS combination still achieved stable performance across different soil properties. Overall, nonlinear algorithms generally yielded lower retrieval accuracy than linear models, with $R^2$ decreasing by 33%–86%. Retrieval accuracy based on multi-view reflectance was consistently higher than that obtained from any single viewing angle. When using single-angle reflectance, retrieval performance varied substantially with view angle. The multi-angle hyperspectral features that improved soil property retrieval were jointly influenced by wavelength and viewing geometry. Near-infrared wavelengths were selected more frequently than visible wavelengths. Although selected feature wavelengths originated from most of the 48 view angles, their relative contributions varied among angles and depended on the specific soil property. Overall, acquiring soil bidirectional reflectance from multiple view angles is preferable for improving soil property retrieval accuracy. Retrieval results based on simulated multi-angle reflectance showed clear improvements compared to those using reflectance from a single view angle. Relative to nadir observations (5°) and the single view angle with the best performance, $R^2$ increased by 17%–42% and 3.7%–8.4%, respectively, across different soil properties. These findings provide valuable insights for enhancing soil property retrieval accuracy using multi-angle hyperspectral observations.

# Physically supervised harmonic framework for spatial characterization of apparent soil thermal diffusivity between 5 and 10 cm.

**M. Francia[1] *, L. Amy[1,2], L. Bentancur[1], R. Alonso-Suárez[2,3]**

[1] *Department ofSoils and Water, Faculty ofAgronomy, Universidad de la República, Montevideo, Uruguay*

[3] *Solar Energy Laboratory, Universidad de la República, Salto, Uruguay*

*martinfrancia@fagro.edu.uy

**ABSTRACT**

Soil thermal diffusivity (KT) controls the attenuation and phase shift of the thermal wave within the soil profile. At the annual scale, KT can be estimated from temperature time series at two depths under the assumption of one dimensional heat conduction (1D) [ 1,2]. The aim of this study was to develop and apply a spatial estimation framework for apparent thermal diffusivity between 5 and 10 cm that combines a statistical harmonic fit supervised by an explicit physical coherence control between depths. Uruguay has daily soil temperature maps at 5 and 10 cm depth estimated from in situ observations and satellite imagery [3]. From these maps, intra annual pixel wise time series were built and the first annual harmonic was fitted by least squares. From these estimates, two diffusivity estimators were derived, one from logarithmic amplitude attenuation and one from the interdepth phase lag. Internal consistency metrics were defined to quantify the mismatch between attenuation and phase lag, as well as a symmetric relative discrepancy between the two estimates. To define global tolerance thresholds, a Monte Carlo procedure was implemented using bootstrap resampling with replacement of paired daily residuals from in situ temperature series, preserving the joint dependence between depths and filtering physically feasible realizations. Under the assumptions of the 1D model, a physical coherence domain (Dphys) was defined for the vector of harmonic parameters by imposing amplitude and phase constraints. The fitted harmonic series are supervised by verifying membership in Dphys and internal consistency relative to the defined thresholds. Local intra annual flags were defined based on vertical temperature differences and residuals relative to the harmonic fit. For series showing locally incompatible behavior, a subset based temporal filtering was applied, which minimizes the exclusion of observations and seeks to recover solutions within Dphys without modifying the data or forcing the observed signal, allowing the time series to express their intrinsic variability within a coherent domain. The presentation will discuss the performance of the physical control and the quality assurance framework in generating annual and typical apparent diffusivity products and their independent validation.

**ABSTRACT**

Understanding the spatio-temporal patterns of soil pH is critical for mitigating cropland soil acidification in southern China. However, croplands in this region are highly fragmented, geomorphological conditions are complex, and most existing regional digital soil mapping approaches exhibit poor spatiotemporal generalization capability. This study aims to develop a robust modeling framework with strong generalization performance for predicting cropland topsoil (0–20 cm) pH in southern China.

Multi-temporal soil survey datasets (1980–2015; n = 20,484) were integrated with corresponding temporal and geographic information, together with 135 static and dynamic environmental covariates. These covariates primarily included 30 m resolution topographic variables, 30 m remote sensing indicators, as well as climate, fertilization, and atmospheric nitrogen deposition variables. The dataset was randomly divided into a training set (70%) and a testing set (30%).

Meta-tasks were constructed by dividing the study area into six geomorphic units (plain, platform, hill, low mountain, mid-mountain, high mountain), with each unit as an independent meta-task for soil pH prediction. A double-loop optimization framework based on Model-Agnostic Meta-Learning (MAML) was employed: in the meta-training stage, the shared feature extractor and meta-network were iteratively optimized to obtain a universal initial parameter set generalizable across geomorphic partitions; in the meta-update stage, these initial parameters were rapidly fine-tuned for each geomorphic meta-task using small-scale samples. This process ultimately produced a globally optimized feature extractor and parameter set applicable to all geomorphic meta-tasks. The predictive framework adopted an ensemble learning strategy integrating four base learners: Partial Least Squares Regression (PLSR), Support Vector Regression (SVR), Random Forest (RF), and Multi-Layer Perceptron (MLP).

The proposed framework significantly outperformed conventional ensemble learning approaches, increasing $R^2$ by 38.49% and reducing RMSE by 6.24%. The pH distribution maps generated by the framework clearly illustrate the pronounced regional acidification over the past four decades. This study provides a high-accuracy framework for long-term regional-scale monitoring and mapping of soil pH, offering valuable scientific support for region-specific soil management and sustainable cropland utilization.

*martinfrancia@fagro.edu.uy

**ABSTRACT**

Soil temperature spatiotemporal variability is controlled by physical factors influenced by parent material. The soil effective thermal properties and the variations in the soil atmosphere energy balance are modulated by mineralogy, structure, the relative water air content, and geomorphology [1,2]. In this study, we evaluated the potential of the soil thermal gradient (G5,10) as a statistically valid indicator to differentiate parent materials across Uruguay, using the national 1:500,000 Geological Map [3] as the References framework. Using monthly soil temperature maps at 5 and 10 cm for 2001 to 2021, previously developed and validated [4], G5,10 was computed and its distribution was compared among all mapped geological units (n = 53). For each month, G5,10 values were grouped by unit and the Kruskal Wallis test was applied, followed by Dunn post hoc comparisons with Bonferroni correction. In addition, the annual thermal singularity of each unit was quantified as the number of significant differences accumulated across the 12 months. Median G5,10 differed among units in all months ($p < 0.0001$). Discrimination strength showed seasonal variability: the number of significant pairs reached a maximum in February (n = 170) and a minimum in November (n = 44). Among parent materials, Cenozoic sedimentary units (unconsolidated coastal and fluvial sediments) and Mesozoic basaltic units showed the highest annual dissimilarity, differing from 42 and 40 units, respectively. In addition, 83% of the units (44 of 53) differed from at least one neighboring unit, indicating sensitivity to contacts. These results support G5,10 as a spatially explicit thermal indicator sensitive to contacts between parent materials, with potential to prioritize areas for verification and boundary refinement using higher resolution surveys.

**ABSTRACT**

Soil salinization is one of the most widespread and rapidly intensifying forms of land degradation, posing a critical threat to food security and ecosystem resilience. Despite extensive in-situ soil salinity measurements through national and global soil databases, spatially consistent and generalizable soil salinity mapping remains constrained by the limited representational capacity of traditional remote sensing features and their sensitivity to regional, temporal, and management variability. Spectral bands and handcrafted indices often require site-specific calibration and show reduced transferability across landscapes and years.

In this study, we present a soil salinity mapping framework that integrates satellite embeddings from the Google Satellite Embedding V1 Annual dataset with environmental covariates to predict electrical conductivity of the soil saturation extract (ECe) across heterogeneous land covers. The annual 10 m satellite embeddings provide a harmonized, multi-sensor representation of land surface conditions, while environmental covariates capture soil-forming factors and hydroclimatic controls on salinization processes. Using field ECe measurements, we train machine learning regression models to link embedding–covariate feature space with observed soil salinity and evaluate performance across regions and years.

Results show that the combined embedding and covariate approach improves predictive robustness and cross-region generalization compared with models relying solely on spectral features and environmental covariates. The embedding-based representation reduces dependence on manual feature engineering and mitigates inconsistencies arising from sensor differences and temporal variability. This work demonstrates how foundation model-derived satellite embeddings, when coupled with environmental context, enable scalable and transferable soil salinity mapping, supporting precision agriculture, land management, and long-term soil health monitoring.

# Spatiotemporal Dynamics and Uncertainty Attribution of 1 km Satellite Soil Moisture Products Across China: A Comparative Assessment via TCH and OPGD

**Jiayi He [1], Xiaojing Liu [*], Baozhuan Zhao[1], Xunjie Ma [1]**

*[1] College of Resources, Sichuan Agricultural University, Chengdu 611130, China*

*E-mail: xiaojingliu@sicau.edu.cn

**ABSTRACT**

Soil moisture (SM) serves as a critical nexus linking terrestrial water, energy, and carbon cycles. However, while 1 km high-resolution products have overcome the spatial constraints of traditional microwave sensors, their performance consistency and error structures across China's complex underlying surfaces remain poorly characterized. To bridge this knowledge gap, this study established a comprehensive evaluation framework by integrating spatiotemporal pattern analysis, Three-Cornered Hat (TCH) uncertainty quantification, and Optimized Parameter Geodetector (OPGD) modeling. We systematically assessed four representative 1 km products—Gap-filled ESA-CCI, SPL2 SMAP, SMCI 1.0, and GSSM1KM—over the period 2003–2020.

Our results demonstrate a pervasive, subtle declining trend in SM across all datasets, marked by significant seasonal periodicity and synchronized interannual fluctuations during 2008 and 2011. Spatially, although a consistent southeast-to-northwest SM gradient is observed, substantial discrepancies emerge in topographically heterogeneous and transition zones. Crucially, TCH analysis reveals a distinct spatial hierarchy of reliability, where SMCI 1.0 exhibits the highest stability (lowest relative uncertainty), whereas SPL2 SMAP shows the greatest uncertainty in complex landscapes. Attribution analysis via OPGD further identifies that annual mean precipitation (AMP) and its interaction with temperature (AMP×AMT) are the primary determinants of uncertainty for most products. In contrast, SPL2 uncertainty is uniquely driven by the interaction between vegetation canopy (LAI) and temperature. Ultimately, these findings clarify the regional applicability of high-resolution SM datasets, providing a vital scientific baseline for product selection and the optimization of retrieval algorithms in climatically diverse regions.

**ABSTRACT**

Digital soil mapping (DSM) often relies on a «one-size-fits-all» approach to remote sensing data processing, applying uniform mosaicking or scene selection techniques regardless of the physical nature of the target soil property. This study, conducted across a 2703-hectare area of the dry Eurasian steppe (Volgograd region), challenges this paradigm by proposing a property-dependent strategy that tailors data processing to the temporal stability of soil attributes.

Using 131 soil samples collected in the summer of 2019 and the Sentinel-2 archive processed via Google Earth Engine, we compared two primary processing groups: (1) per-pixel temporal compositing (6 scenarios) and (2) per-date scene selection (2 scenarios). Our results reveal a clear methodological dichotomy. Stable soil properties, specifically soil texture, are best predicted using per-pixel temporal compositing, which acts as a temporal filter to minimize spectral noise from transient surface conditions ($R^2$ up to 0.56 for sand and 0.51 for silt). In contrast, dynamic properties, particularly soil moisture, benefit from per-date scene selection that captures a coherent «physical snapshot» of the landscape ($R^2$ = 0.41 for moisture using the driest-scene approach).

Furthermore, we integrated physical geomorphometry (PG) variables, representing the energetic potential of the landscape and legacy soil data as covariates. Variable importance analysis demonstrated that while legacy data provides a critical pedogenetic baseline for zonal Kastanozems and Solonetz complexes, PG variables (e.g., Index of Slope Energy Disequilibrium) are vital for predicting structurally dependent properties like soil erodibility (K-factor) and bulk density. We synthesize these findings into a «Process-Property-Strategy Framework» offering a dual-component solution for precision agriculture: a «Strategic Base Map» for long-term planning (stable properties) and a «Tactical Monitoring Layer» for in-season management (dynamic properties). This research provides a robust methodological foundation for the next generation of property-specific DSM services.

# Innovation in Large-scale Soil Pollution Investigation Driven by Multi-source Data: A Transition from Grid-based to Precision-based Approaches

**Guanlin Guo[1], Tingting Fang[1], Jinfeng Wang[2], Tianyang Wang[1], Fengbei Shen[2], Yan Li[1], Juan Wang[1], Wenjuan Ding[1]**

## ABSTRACT

Soil pollution, characterized by its cumulative nature, heterogeneity, and invisibility, poses a significant challenge to the sustainable utilization of global land resources. Traditional large-scale investigation methods often suffer from inadequate spatial representation and insufficient reliability in trend assessments, making it difficult to meet the demands for precise soil environmental risk management. To address these issues, this study proposes a precision-based investigation technical framework that integrates multi-source data with spatial differentiation statistics, the core framework of which covers five links: "pollution impact range identification—spatial unit partitioning—differentiated investigation—trend prediction—classified control", aiming to achieve a transition from grid-based investigation to precision-based investigation. The technical system first utilizes knowledge graphs and machine learning methods to integrate pollution source inventories, land use, and historical monitoring data to construct an evaluation matrix of "pollutant toxicity—emission intensity—migration capacity," quantifying the impact range of industrial point sources and agricultural non-point sources. Secondly, based on the principles of spatial differentiation statistics, homogeneous investigation units are partitioned by combining environmental factors and land use characteristics to achieve refined zoning for types such as agricultural and construction land, and a spatial sampling optimization model is applied to generate cost-controlled sampling schemes. In the trend prediction link, panel data is integrated with long-term observation information, and policy and flux analyses are coupled to construct a comprehensive soil pollution change prediction model, improving the reliability of trend assessments. Finally, the pollution status of each land use patch is presented intuitively through a "Red-Yellow-Green" map, aligning with ecological environment partitioning and spatial planning requirements to support classified and hierarchical management. Application results demonstrate that this technical framework can significantly improve the accuracy of source-sink relationship analysis and investigation efficiency, providing an innovative technical path for global large-scale soil pollution investigation and contributing to the goal of "comprehensive soil environmental risk management" for a beautiful China.

**ABSTRACT**

Widespread soil acidification due to atmospheric acid deposition and agricultural fertilization can significantly accelerate soil carbonate dissolution and CO2 release. Here, we collected nationwide and global soil datasets and developed machine learning and process-based models to quantify the spatiotemporal changes in soil inorganic carbon (SIC) stocks. Three conclusions were achieved as follows. (1) We observe an overall decrease in SIC stocks in topsoil (0–30 cm) (11.33 g C m–2 yr–1) across China's cropland, forest and grassland from the 1980s to the 2010s. Total SIC stocks have decreased by~ 8.99±2.24% (1.37±0.37 Pg C) (Song et al., 2022). (2) Global soils store 2305 ± 636 (±1 SD) Pg C as SIC over the top 2-meter depth. Machine learning-based models identify that soil pH acts as the most important predictor for the variation in SIC (29%). Under future scenarios, soil acidification associated with nitrogen additions to terrestrial ecosystems will reduce global SIC (0.3 meters) up to 23 Pg SIC over the next 30 years, with India and China being the most affected (Huang et al., 2024). (3) Finally, we develop a new process-based Soil Inorganic Carbon Turnover Model (SINCOM) to quantify the impacts of climate change on SIC dynamics from 2015 to 2100 across China. SINCOM integrates a physically-based soil water balance module with a carbonate geochemical equilibrium, excluding acidification processes to isolate climate-driven effects on SIC. We find a decrease of 209–225 Tg C in SIC stock in 0–2 m soils under four Shared Socioeconomic Pathways, with higher loss rate in humid regions (281–960 mg C m-2 yr-1) than those in arid regions (6–29 mg C m-2 yr-1).

**ABSTRACT**

Currently, generating quantitative Soil Taxonomic Classification maps from legacy Soil Genetic Classification maps relies primarily on direct taxonomic correlation. However, this method often yields substantial mapping errors, especially in large, flat regions with weak environmental gradients. To address this, we propose an innovative framework of "first directly correlating the legacy soil map to extract pseudo points, followed by zonal optimization." This framework was validated in China's Songnen Plain, one of the most challenging large flat terrains, with the aim of providing a new solution for developing high-quality localized Soil Taxonomic Classification maps. Initially, a 1:1,000,000 Soil Genetic Classification map was directly correlated to produce a map of Chinese Soil Taxonomy (CST) , achieving an initial accuracy of only 44%. Subsequently, a digital soil mapping approach based on hierarchical zoning was implemented. This involved partitioning the area according to a hierarchical framework, extracting pseudo points within each zone, integrating multi-source environmental covariates, and finally performing spatial prediction of soil classes using a multi-level random forest model. The results demonstrate that the zonally optimized map achieved an overall accuracy of 53%, significantly outperforming both the direct correlation result and a conventional whole-area modeling approach (which yielded an accuracy of only 25%). This confirms the effectiveness of the proposed framework for achieving high-accuracy soil type mapping in flat regions. Our study provides a referable technical pathway for the cost-effective and robust updating of soil maps in large, flat regions worldwide.

# Future Projections of Global Belowground Net Primary Productivity in Response to Climate Change

**ABSTRACT**

Belowground Net Primary Productivity (BNPP) refers to the net photosynthetic products allocated by plants to the belowground parts through their root systems, serving as a crucial factor influencing the accumulation and stability of soil organic carbon. Under global climate change, BNPP exhibits high sensitivity to the global carbon cycle and ecosystem adaptive capacity, making its accurate quantification scientifically important for understanding ecosystem functions and developing effective climate change strategies. However, existing model-based assessments of environmental factors contributions to BNPP remain limited, and quantitative analyses of BNPP trends under different climate scenarios are still lacking. This study integrates global BNPP observational data with multi-source datasets, including climate, soil, and topographic variables. We employed XGBoost Residual Kriging (XGBRK) to simulate the spatial distribution of BNPP at 0–2 m depth. SHapley Additive exPlanations (SHAP) analysis was applied to evaluate the influence of different environmental variables on BNPP. In addition, Coupled Model Intercomparison Project Phase 6 (CMIP6) climate model data were utilized to project future BNPP dynamics under different emission scenarios. The results indicate that: (1) the global mean BNPP is 1.782 $Mg \cdot ha^{-1} \cdot yr^{-1}$ witn tropical forests (2.501 $Mg \cdot ha^{-1} \cdot yr^{-1}$) and warm temperate forests (2.585 $Mg \cdot ha^{-1} \cdot yr^{-1}$) exhibiting the highest BNPP values, whereas tundra ecosystems show the lowest (0.724 $Mg \cdot ha^{-1} \cdot yr^{-1}$); (2) Among the environmental factors, climate variables are the primary drivers of BNPP (SHAP: 59.5%), followed by soil properties (24.6%), with topographic variables contributing the least (15.9%), and significant differences were evident among various biomes; (3) In the future (2081-2100), global BNPP shows an overall increasing trend (~0.05 $Mg \cdot ha^{-1} \cdot yr^{-1}$), which is particularly pronounced under the high-emission scenario (SSP5-8.5), while warm temperate forests are the only biome exhibiting a productivity decline. Our findings confirmed that climate is the dominant factor influencing BNPP spatial distribution, followed by soil properties, while topography has a relatively minor effect. Although the future spatial pattern of BNPP remains broadly consistent with the current distribution, intensifying emission scenarios may drive some biomes toward their ecological adaptation thresholds, thereby weakening the differences among biomes.

# A Multi-Source Product Assessment and Uncertainty-Aware Modeling Framework for SOC Mapping in China

*E-mail: xiaojingliu@sicau.edu.cn

**ABSTRACT**

Soil Organic Carbon (SOC) is pivotal for terrestrial carbon cycle research, yet the reliability of current products is often compromised by discrepancies in data sources and mapping methods. To address spatial uncertainty hindering decision-making, this study developed a comprehensive framework coupling robust validation with explainable modeling to optimize SOC mapping in China. The study involved two phases. First, four mainstream products—HWSD V2.0, SoilGrids 250m V2.0, CSDL V2.0, and the China High-Resolution Grid—were evaluated using benchmarks from the 2nd National Soil Census and the Soil Series of China. The Three-Cornered Hat (TCH) method was applied to quantify relative error variances independent of ground truth. Second, guided by a bibliometric review, eight algorithms (e.g., SVM, XGBoost, QRF, RFRK) were compared via 10-fold cross-validation to assess prediction accuracy (RMSE) and uncertainty validity (PICP), while SHAP (SHapley Additive exPlanations) analysis was used to identify environmental drivers. Results indicate that product suitability varies spatially across different landscapes, while TCH analysis confirmed that relative noise distribution is significantly modulated by topographic heterogeneity, with higher uncertainty in hilly regions. Regarding modeling, Random Forest Regression Kriging (RFRK) yielded the highest prediction accuracy, whereas Quantile Regression Forests (QRF) offered the most reliable uncertainty quantification. Furthermore, SHAP analysis identified Mean Annual Precipitation (MAP) and other key factors as dominant drivers, crucially revealing that interpretation reliability decreases in complex terrains. Ultimately, this framework enhances the transparency and accuracy of SOC mapping, providing the reliable data foundation necessary for delivering effective global soil services and solutions.

## ABSTRACT

Soil data and knowledge, despite its critical role in sustainable land management and environmental stewardship, has long been hindered by significant obstacles in terms of accessibility, interoperability, and reusability. From the perspective of the FAIR (Findable, Accessible, Interoperable, and Reusable) principles, many soil datasets remain siloed, difficult to discover, and challenging to integrate across different platforms and research contexts. These challenges have limited the broader potential for informed decision-making and cross-disciplinary collaboration in soil science.

The SoilWise project directly addresses these obstacles by democratizing access to digital soil data including knowledge through innovative technologies and a user-centric platform. By aggregating metadata from more than a dozen leading open repositories, including Zenodo and OpenAire, SoilWise has successfully harvested over 30,000 metadata assets that span from local soil mapping campaigns to global soil data, all available through the SoilWise catalogue. This vast repository helps overcome the "findability" and "accessibility" barriers by centralizing and standardizing soil data in an open-access framework.

A key achievement of the project is the identification and resolution of data duplicities, which enhances data quality and interoperability, ensuring that users can trust the datasets they access and apply them across varied contexts. To further support the FAIR principles, the project has developed comprehensive guidelines and strategies for ensuring that soil data is both reusable and reusable at scale. These include the use of standardized metadata, persistent identifiers, and clear data documentation, as well as the adoption of shared vocabularies and ontologies to facilitate seamless data integration.

To improve user experience and broaden adoption, SoilWise has also integrated a ‘Soil Companion’ chatbot, offering real-time guidance, and developed clear guidelines that help users navigate the platform and make the most of the data available. By promoting a holistic and FAIR-compliant approach to soil data management, SoilWise fosters a more collaborative and data-driven approach to soil science, enabling researchers, policymakers, and land practitioners to make better-informed decisions for sustainable land use and soil management. This presentation will explore these achievements, illustrating how SoilWise is advancing the democratization of soil data on a global scale.

## ABSTRACT

Soil texture should be obtained at a useful scale for sustainable agricultural energy and food systems in colluvium-alluvial plains. Ground Penetrating Radar (GPR) can collect data in a non-destructive and rapid manner to assist in soil texture prediction. In this study, the objective was to evaluate the effect of geophysical data such as electromagnetic wave time (EMWT), electromagnetic wave amplitude (EMWA), and dielectric constant (K) extracted from GPR profiles on predicting clay and sand contents. We also explored the impact of use and non-use gravimetric water content (GWC) as a predictor covariate. The use of variable selection tools in machine learning (ML) algorithms was evaluated, and the nested holdout by GPR profile method was optimized for training and selecting suitable models for prediction. Soil samples were collected at 59 soil cores at 0.20 m intervals up to a depth of 1 m (total 5 layers), along with a hand auger to assess the variation textural and GWC. Data from GPR profiles were extracted for each soil core in the 5 layers to relate them to soil texture data and GWC. Morphometric parameters were obtained from a Digital Terrain Model (pixel size 5 m). ML algorithms including Cubist, Random Forest (RF), Support Vector Machine (SVM), and a Linear Model (LM) were compared. Results were trained and validated using an optimized nested holdout test by GPR profile. Covariate modeling with selection by near-zero variance, correction removal, and importance removal was necessary for model parsimony, with covariates related to sedimentological processes. The covariate with 100% importance in predicting clay and sand contents was GWC for the Cubist, RF, and SVM models. 'Depth' as a covariate showed a mean relative importance ≥ 75% for the prediction of clay, and > 50% for sand content in the Cubist and RF models, indicating a higher sand contribution in deeper layers. The covariates extracted from the GPR profiles, EMWT figure in the top 10 main predictors of clay content for the Cubist, RF, and LM models. Sand content was an important predictor in the RF and LM models. EMWT reduces the subset of covariates in the models and improves predictive performance. Soil texture predominantly presented a clay textural class, which interfered with the lower importance of EMWA and K covariates. The models with the best performance were Cubist and RF for predicting clay (LCCC 0.432 and 0.410, respectively) and sand content (LCCC 0.505 and 0.506, respectively), differing only in $R^2$ according to the Kruskal-Wallis test. Clay and sand contents in sedimentary environments were efficiently modeled using optimized ML techniques and a dataset combining morphometric, electromagnetic, and GWC data across depths. Future studies should further explore the application, particularly of EMWT, as a covariate in ML models. Our approach provides a more efficient and optimized method for texture prediction in sedimentary environments in subtropical forests.

# Integrating Proximal and Remote Sensing to Cross-scale Quantify Soil Organic Carbon and Moisture Dynamics via Multi-model Learning

**Sheng Wang**[1]*

[1] *Pioneer Center Land-CRAFT, Department of Agroecology, Aarhus University, Aarhus, 8000, Denmark*

*E-mail: swan@agro.au.dk

**ABSTRACT**

Soil organic carbon (SOC) and soil moisture (SM) are fundamental variables for soil health and ecosystem functioning. However, consistent quantification of their spatial patterns and temporal dynamics from local to global scales remains challenging due to scale mismatches, sensor heterogeneity, and complex soil–environment interactions. Bridging proximal and remote sensing is essential for scalable and physically meaningful soil monitoring. Here, this study presents a cross-scale framework that integrates proximal soil sensing (i.e., SOC spectroscopy libraries, field time-domain reflectometry and cosmic-ray SM sensors), airborne-satellite remote sensing, and process-based soil-vegetation-atmosphere radiative transfer models to quantify surface SOC and SM dynamics from local to regional or global extents. Proximal optical spectroscopy and SM sensors capture soil organic carbon and moisture-related signals accurately, while satellite remote sensing provides broader scale signals on surface SOC and SM across diverse conditions. These complementary data streams are fused using a multi-model learning approach that combines data-driven machine learning and process-based models via knowledge-guided machine learning. Results show that explicitly integrating proximal and remote sensing reduces domain gaps, improves cross-scale generalization, and enhances the estimation of SOC and SM across heterogeneous landscapes. The proposed framework advances scalable soil monitoring and supports applications in regional or global soil assessment, land management, and Earth system science.

## ABSTRACT

Understanding the relationship between land surface temperature (LST), soil moisture (SM), and vegetation (V) is crucial for evaluating the impacts of climate change in arid and semi-arid regions. Iran, a country predominantly characterized by such climates, presents a critical case study. Its complex topography, featuring the high-altitude Alborz and Zagros Mountain ranges, the vast central deserts (e.g., Dasht-e Kavir and Dasht-e Lut), and narrow coastal plains along the Caspian Sea and Persian Gulf, creates sharp climatic gradients. This results in a spectrum from hyper-arid to humid subtropical zones, making its ecosystems highly sensitive to hydro-climatic fluctuations.

This study provides a large-scale spatiotemporal analysis of LST, surface soil moisture (SSM), and vegetation dynamics across this topographically and climatically diverse nation over a 30-year period (1995–2025) using satellite remote sensing data. Multi-temporal Landsat (5 TM, 7 ETM+, 8 OLI/TIRS, and 9 OLI-2/TIRS-2) imageries were processed in the Google Earth Engine (GEE) cloud-computing platform to derive annual cloud-free LST composites and vegetation indices (NDVI, SAVI). SSM was estimated using the OPTRAM (Optical Trapezoid Model), a physically-based method that leverages the empirical relationship between shortwave infrared transformation, vegetation index, and soil moisture within the LST-vegetation index feature space. Temporal trend analyses, including the Mann-Kendall and Sen's slope estimators, were applied to investigate long-term changes in LST, SSM, and VIs. Spatial analyses, including correlation and hot-spot analysis (Getis-Ord Gi*), were conducted to examine their co-variability across Iran's distinct climatic regions. Furthermore, relative change metrics were calculated to identify areas experiencing notable shifts in soil moisture conditions and associated vegetation response over time.

The results indicate significant spatial and temporal variability in LST, SSM, and vegetation across the study area. Notably, the arid interior basins and semi-arid northwestern regions show concurrent and statistically significant warming trends, SM decline, and V stress. In contrast, some northern and highland areas exhibit more stable or complex patterns. The generated maps provide an integrated overview of potential climate-related SM and V dynamics and identify regions, particularly in central, eastern, and southwestern Iran, that appear more sensitive to long-term environmental change and land degradation. This study demonstrates the value of combining long-term satellite observations, RS–based SM models like OPTRAM, and vegetation indicators within an integrated analytical framework (e.g., GEE) for national-scale assessments of soil–climate–vegetation interactions. The findings offer an empirical basis for targeted climate adaptation and land management strategies in vulnerable arid regions.

**ABSTRACT**

Reliable and accessible soil information is essential for sustainable land management, yet existing digital soil mapping (DSM) approaches often rely on sparse ground data, high sampling costs, and limited usability for non-technical stakeholders. This creates substantial uncertainty in estimating soil organic carbon (SOC) stocks, soil biodiversity, and related ecosystem functions. SOCBIO-MAP addresses these challenges by combining Earth observation (EO), AI-based modelling and optimized in-situ sampling to deliver scalable, cost-efficient and transparent soil information services. The approach responds directly to global needs identified in current DSM discourse, including the integration of multisource data, increased resolution, and democratized access to soil intelligence.

SOCBIO-MAP fuses predictors from various EO sensors (including multi-spectral and SAR) with DEM's and targeted soil sampling guided by EO-driven optimization. This workflow aims to minimize field sampling numbers while maintaining model accuracy, enabling reliable SOC stock estimation across heterogeneous landscapes in Chile and Paraguay. Soil laboratory analyses, including physicochemical properties, SOC content, bulk density and eDNA-derived biodiversity metrics, strengthen model training and validation. By unifying EO, laboratory and field-based measurements, the project overcomes the disconnect between point-based observations and landscape-scale prediction for carbon market stakeholders.

A key outcome is the creation of high-resolution SOC, biomass, and biodiversity geolayers that improve upon existing global datasets and are applicable across forest and agroforestry systems. These outputs will be deployed in a visualization platform, offering intuitive dashboards that support decision-makers, carbon project developers, conservation NGOs, and certification bodies. The system provides an accessible interface for understanding soil health, mapping co-benefits, and strengthening MRV processes in voluntary carbon and biodiversity markets.

The project contributes to the democratization of DSM by reducing technical barriers, improving data transparency and providing scientifically validated, easily interpretable soil information. Ultimately, SOCBIO-MAP strengthens global capacity to monitor soil health, supports evidence-based land management and advances high-integrity nature-based solutions aligned with climate, biodiversity and sustainability goals.

**ABSTRACT**

Digital Soil Mapping (DSM) can obtain a large amount of soil data, which can offer critical data support for revealing the mechanisms underlying soil landscape evolution. Soils exhibit various development trends due to differences in initial conditions and external driving forces, leading to the spatial and temporal variation in their properties. This study integrates DSM with a modified evolutionary pathway approach which is based on Δcomplexity. Horizontal and vertical soil heterogeneity across an agro-pastoral transitional zone (APTZ) in northern China was quantified. Particle size distribution (PSD) and magnetic susceptibility (MS) were focused on, and, on the basis of soil property resulting maps, Δcomplexity between different soil depths was quantified to provide valuable insights into soil-landscape evolution. This study measured the PSD and MS of 1317 samples and determined Δcomplexity for 148 catchments in the study area. The $R^2$ for the prediction accuracy of DSM ranged between 0.481 and 0.729. The Δcomplexity of PSD spans from -0.089 to 0.042 % $cm^{-1}$ for both deep and shallow layers, whereas that of MS ranges from -0.6 to 0.96 10-8 $m^3$ $kg^{-1}$ $cm^{-1}$. Vertical heterogeneity, which is determined by the positive or negative shifts (convergent or divergent) in Δcomplexity in every 5cm soil, is primarily associated with soil forming factors such as parent material, topography and vegetation, and it is further regulated by tree throw and human activities. For horizontal heterogeneity, which derived from pedogenesis and also soil redistribution induced by both water and wind erosion, is determined by the positive and negative variations in both shallow and deep complexity. Our approach enables the identification of highly heterogeneous areas that may be particularly sensitive to soil change and degradation. It offers a transferable framework for assessing soil development and guiding sustainable land use. Δcomplexity can be used to capture the dynamic changes in soil properties along the soil profile on the basis of the large amount of data obtained from DSM, the combination of DSM and the soil Δcomplexity metric provides a promising tool for analyzing and visualizing the state and trends of soil-landscape evolution.

# Projected intensification of soil salinization in global drylands under future aridity increase

## ABSTRACT

Soil salinization is a major threat to agricultural production, water management, and ecosystem health. Although climate change is projected to expand global drylands, the response of future spatiotemporal changes in global drylands soil salinity, especially in croplands, to increased aridity remains unclear. Here, we develop machine learning prediction models using the last 20-year global soil salinity measurements combined with climatic, anthropogenic, geological, and remote sensing data to provide future changes in soil salinization. Our results reveal that saline soil areas in drylands are projected to expand with rising aridity. In dryland croplands, transitions to saline soils are projected to occur predominantly within irrigated areas. These findings offer crucial insights into the future changes in dryland saline soils around the globe, thus informing the development of more effective soil salinity monitoring and management strategies.

# Spatial distribution and formation environment of rock fragment layer in black soil region of northeastern China

**ABSTRACT**

Soil gravel plays a crucial role in regulating water-air transport and ecological processes. Due to complex pedogenic processes, the spatial distribution of soil gravel often exhibits high heterogeneity, making accurate mapping of its spatial distribution a challenging task. This study collected 1,176 soil profile data points from the black soil region of Northeast China (427 profiles with gravel and 749 without gravel). By integrating topographic and multispectral remote sensing data, a random forest model was employed to predict the spatial distribution of soil gravel in the region. The predictive model was evaluated using 30% of the data as validation, achieving a ROC-AUC of 0.83 and an F1-score of 0.74. The prediction results indicate that the probability of soil gravel occurrence is high in the following areas: the river floodplains of the Songhua River basin in the Sanjiang Plain, the river valley zones of the Songliao Plain along the middle reaches of the Liao River, and the foothill slopes and gullies of the Greater and Lesser Khingan Mountains and the Changbai Mountain range. The study also conducted an in-depth uncertainty analysis and revealed factors influencing the spatial differentiation of gravel layers. The distribution of soil gravel is affected by topography and land use types, which aligns with the finding that MRVBF and soil thickness hold the highest importance in the predictive model. The machine learning model developed in this study can provide reliable data support and technical methods for accurate carbon stock estimation, cultivated land quality monitoring, and sustainable land resource management in the black soil region of Northeast China.

**ABSTRACT**

Alpine meadows in the Qinghai-Tibetan Plateau (QTP) play a crucial role in global carbon and nitrogen cycles. Due to the unique environmental conditions and complex soil processes in the region, accurately quantifying the spatial distribution of soil organic carbon (SOC) and total nitrogen (TN) concentrations in these ecosystems remains a major challenge. The study effectively utilized UAV-based digital elevation models (1-m resolution), spectral data, and machine learning techniques (i.e., geographical weighted regression, gradient boosting regression tree, random forest, combined with residual kriging) to predict SOC and TN in the mattic layer of the typical alpine meadow ecosystem of the QTP. A total of 62 soil samples from the mattic layer were collected from the study area, and the mattic layer depth was also recorded. The performance of the prediction models were evaluated on 30% test data considering R2, MAE, and RMSE. The random forest residual kriging model provided the highest prediction accuracy for SOC and TN, with $R^2$both being 0.69, MAE 12.39 and 0.36, respectively, and RMSE 14.83 and 0.46, respectively. The SOC content of the soil in the mattic layer of the meadow ecosystem is 51.36-106.90 g $kg^{-1}$, and the total nitrogen content is 3.41-5.81 g $kg^{-1}$. The study also conducted an in-depth analysis of uncertainty and revealed the factors affecting the distribution of SOC and TN. Areas with large topographic fluctuations had higher uncertainties in the distribution of SOC and TN. Topography was the most important factor controlling the distribution of SOC and TN. These results provide valuable insights into predicting the carbon sequestration potential of alpine meadows, which is crucial for global climate regulation, and the maps can be useful in grazing and soil management priorities. Future research will test prediction models by utilizing anthropogenic factors such as grazing intensity and additional sampling from high-uncertainty areas and assess their importance and interpretations.

# Development and Applications of a Soil Spectral Library in Hainan, China

**Zhen Wang[1*], Tianqi Lv[1], Jianping Qian[1]**

[1] *Institute of Agricultural Resources and Regional Planning, Chinese Academy of Agricultural Sciences, Beijing, China*

*wangzhen02@caas.cn

**ABSTRACT**

Soil organic matter (SOM) is a key indicator of soil quality, agricultural sustainability, and the carbon cycle. Visible–near infrared (Vis–NIR) spectroscopy enables rapid, non-destructive soil assessment, but model robustness remains limited in tropical regions where intense weathering, acidic conditions, Fe/Al oxide enrichment, and diverse land use create complex spectral backgrounds. This study presents a regional soil spectral library for Hainan Island, China, and its application for SOM prediction.

From May to July 2025, a large-scale spectral campaign was conducted in Haikou using samples from the Third National Soil Survey. Approximately 6,000 soil samples were organized, about 4,800 laboratory spectra of 2-mm sieved samples and 3,000 moisture experiment spectra were acquired, and around 6,000 physicochemical records are expected to be linked. A standardized workflow was established for sample preparation, white-References calibration, spectral scanning, preprocessing, and data storage. Digital tools supported sample–spectrum registration, batch renaming, spectral averaging, and standardized output. The library links sample identity, metadata, spectra, physicochemical properties, and quality-control information.

Two applications demonstrate its value. First, a texture-aware framework was tested using 270 agricultural topsoil samples classified as sandy, loamy, and clayey soils. Spectra were processed using SNV and SNVBA; CARS was used for feature selection; and PLSR and RF models were compared. Texture affected spectral behavior and model performance. SNVBA improved loamy and clayey spectra, while CARS mainly benefited PLSR. RF achieved high and stable performance across texture and preprocessing combinations, with most $R^2$ values above 0.85. These results support texture stratification, preprocessing adaptation, and RF-based nonlinear modeling.

Second, a mechanism-guided covariate compensation strategy was developed using 608 highly weathered tropical acidic topsoil samples. Bayesian network analysis identified DTPA-extractable Fe (AFe) as a key background variable associated with SOM spectral responses. Band-wise correlation revealed SOM–AFe spectral overlap, especially around 1550–1750 nm, indicating that overlap bands contain both SOM information and Fe-related interference. Removing overlap bands alone did not clearly improve prediction. In contrast, adding water content, electrical conductivity, and AFe improved PLSR performance. The final fusion model achieved $R^2 = 0.670$, RMSE = 2.92 g $kg^{-1}$, RPD = 1.77, and RPIQ = 2.19, increasing $R^2$ by about 59.9% and reducing RMSE by about 24.7%.

Overall, the Hainan Soil Spectral Library is a standardized, traceable, and scalable prototype for tropical soil spectral infrastructure. By combining library development, texture-aware modeling, and mechanism-guided covariate compensation, this study provides an interpretable pathway for robust SOM prediction in highly weathered tropical soils.

**ABSTRACT**

Rapid in situ field quantification of soil constituents remains a global challenge. Inspired by the SuperCam spectroscopic technology deployed on NASA's *Perseverance* Mars rover, we pioneered a novel methodological and theoretical framework for multimodal laser spectroscopic sensing of agricultural soils. Based on this framework, we led the development of an on-site field sensor capable of directly and accurately measuring multiple soil nutrients and contaminants under field conditions.

**Theoretical advances:** We established the field of multimodal laser soil spectroscopy by enabling synchronous measurements of scattering, absorption, and fluorescence through a shared optical path, together with deep fusion of multimodal signals. To address key bottlenecks such as the highly complex soil matrix and the ultratrace concentrations of heavy metals, we developed a new fluorescence-resonance LIBS sensing paradigm, which enhances signal intensity by 2–3 orders of magnitude and enables rapid detection of heavy metals down to 150 *ppt*, setting a new record for the lowest detection limit in spectroscopic sensing. We also proposed a new theory of laser-ablation-coupled absorption spectroscopy and, for the first time, achieved rapid in-field detection of soil microplastics.

**Technological application:** We developed the in situ soil sensor "SmartSoil", which can measure three major categories of soil properties—nutrients, heavy metals, and trace elements—covering 36 indicators within 10 minutes. These include total nitrogen, nitrate nitrogen, available phosphorus, multiple heavy metals, microplastics, and other key parameters. The system is supported by independent intellectual property rights and protected by 16 Chinese invention patents and 3 international patents. "SmartSoil" has been selected for the "Sci-Tech Innovation China" Pioneer Technology List, the Top 10 Original Smart Agriculture Solutions for Beijing Smart City Scenarios, the National Top 10 Recommended Technologies for Smart Agriculture Science and Innovation, and the Beijing Catalogue of First Major Technological Equipment.

**ABSTRACT**

Soil acidification is a critical constraint on sustainable agriculture in tropical regions where accurate soil pH mapping is essential for informed soil management and ecological assessment. However, existing digital soil mapping (DSM) approaches often struggle to capture both the complex nonlinear relationships among environmental covariates and the spatial dependence inherent in soil pH, especially for at a regional scale. To address this gap, we developed a hybrid modeling framework that integrates ensemble machine learning with spatial residual correction. Using Chengmai County located in south China as a case study, soil pH observations were combined with multisource environmental predictors, including long-term remote sensing imagery, topographic variables, and historical soil information. A stacking ensemble model, built from Random Forest, XGBoost, and CatBoost, was first trained to capture nonlinear patterns. The residuals from this model were then refined using Geographically Weighted Regression (GWR) to account for local spatial variation. Results demonstrate that integration of ensemble learning with spatial regression substantially improve the accuracy of soil pH mapping (R2 of 0.67). This approach provides a robust tool for monitoring soil acidification and guiding sustainable agricultural management in tropical croplands.

## ABSTRACT

Soil moisture status is crucial for agricultural drought assessment. The satellite-derived Soil Moisture Active Passive Level-4 (SMAP L4) modelled root zone soil moisture (RZSM) product, with its 9 km spatial resolution, is suitable for this purpose. However, its availability from 31st March 2015 onwards limits its applicability for the computation of robust drought indices. To address this gap, we used an ensemble machine learning approach—Random Forest (RF) regression with dynamic and static inputs—which outperformed other models on the independent 2021 validation set, achieving the highest coefficient of determination ($R^2$ = 0.74–0.81) and the lowest root mean square error (RMSE = 0.026–0.044), compared with Artificial Neural Networks ($R^2$ = 0.19–0.32, RMSE = 0.083–0.175), Support Vector Machines ($R^2$ = 0.03–0.27, RMSE = 0.063–0.125), and Classification and Regression Trees ($R^2$ = 0.65–0.73, RMSE = 0.032–0.052). This trained RF model predicted SMAP L4 RZSM for 2001-2015, combining with actual data from 2016-2021 to form a 21-year continuous long-term dataset used to compute the Soil Water Deficit Index (SWDI, Martínez-Fernández et al., 2015) and its standardized form, Standardized Soil Water Deficit Index (SSWDI). The SSWDI mitigated the SWDI's tendency to overestimate drought areas and proved more effective for capturing droughts during the monsoon *(kharif)* crop season across India. The SSWDI accurately identified maximum drought-affected areas in known severe years such as 2002, 2009, 2012, 2014, and 2015, as reported by government agencies, and showed a stronger correlation with the 3-month Standardized Precipitation Index (0.45) compared to the trend-adjusted Vegetation Condition Index (0.28). Additionally, SSWDI showed a strong correlation with the Standardized Normalized Agricultural Gross Primary Productivity (SNGPP; $p < 0.1$, $R > 0.6$)—computed by removing the technological time trend from Agricultural Gross Primary Productivity (Gangopadhyay et al., 2022)—particularly in rainfed regions and the late crop season. By leveraging site and spatial data with machine learning to extend SMAP RZSM, this work provides a nationally consistent soil moisture baseline and a robust, standardized drought index SSWDI, tailored for agricultural drought monitoring. Future work could integrate multiple indicators such as rainfall, soil moisture, evapotranspiration, and vegetation into a comprehensive drought index for even more holistic drought monitoring.

# Soil Fertility Index and Spatial Variability as Drivers of Site-Specific Fertilizer Management in the Tigray Highlands

**Mulugeta Sebhatleab[1]*, Girmay Gebresamuel[1], Gebreyohannes Girmay[1], Mitiku Haile[1]**

*[1] Land Resources Management and Environmental Protection, Mekelle University, Mekelle, Ethiopia*

** Correspondence: mulugeta.sebhatleab@mu.edu.et or mulusk96@gmail.com*

**ABSTRACT**

Agriculture is central to Ethiopia's economy, yet increasing population pressure and unsustainable farming practices have led to severe soil fertility depletion and land degradation, particularly in the Tigray region highlands. This study assessed soil properties conditions in the Seret and Adigolo sites of Tigray region, aiming to develop the Soil Fertility Index (SFI), identify its key determinants, and support the development of site-specific fertilizer recommendations. The research was conducted using field surveys, grid-based soil sampling, laboratory analysis, Principal Component Analysis (PCA), and GIS-based spatial interpolation for soil property mapping. It was identified that there was significant variability in soil properties across the sites. Both Seret and Adigolo soils were characterized by nearly neutral pH, low EC, and high cation exchange capacity (CEC), indicating favourable conditions for crop production. However, both sites showed critical nutrient limitations particularly low levels of available P, Zn, TN, and low to moderate SOM primarily due to continuous cultivation, poor organic input, and erosion. PCA revealed six minimum soil fertility indicators (MSFIs) most relevant to assessing soil health, and these were used to calculate the SFI. Spatial analysis showed that almost 100% of farmland in Adigolo had Moderate SFI and, compared to 94.3% moderate and 5.7% low in Seret site. These differences reflect varying land management and soil fertility status. These results emphasize the need for site-specific fertility management using organic amendments, macronutrients and micronutrients mineral fertilizers, and conservation practices to sustain productivity. The SFI can be used as a diagnostic tool for guiding tailored interventions that improve input use efficiency, maintain yield performance and enhance smallholder livelihoods.

**ABSTRACT**

Soil organic carbon (SOC) is central to regulating the global carbon cycle and underpinning food security, yet unsustainable cultivation has resulted in a continuing SOC loss and has made it highly vulnerable to climate change. In China, the Well-Facilitated Farmland Construction (WFC) initiative has sought to enhance soil conditions by integrating farmland management units (FMUs) and adopting improved practices, including optimized irrigation, straw incorporation, and targeted fertilization strategies. Since its launch in 2013, the WFC project has been implemented across more than 50 million hectares of farmland in China. However, its spatio-temporal impacts on SOC remain poorly understood. To address this gap, we focused on three representative regions, Shunyi, Rudong, and Dangtu, to examine the impact of FMU integration. A total of 1,549 soil profiles were compiled to calibrate the process-based CENTURY model and simulate long-term variations in topsoil (0-20 cm) SOC density (SOCD) across Chinese farmlands. Results show that, following the WFC project, farmland fragmentation decreased while SOCD increased, with strong negative correlations between fragmentation degree and SOCD (-0.88 in Shunyi, -0.94 in Rudong, and -0.52 in Dangtu). These findings indicate that farmland patch integration contributes significantly to SOC sequestration. By comparing future SOC trajectories under traditional versus WFC practices, we found that WFC management offers substantial sequestration potential, increasing SOC stocks by 3.34 Pg under SSP1-2.6 and 2.86 Pg under SSP5-8.5 during 2030-2100 in Chinese farmlands. This sustained increase reflects the synergistic effects of fertilization and elevated $CO_2$, enhanced crop productivity through optimized irrigation, greater organic inputs from straw incorporation, and reduced microbial decomposition under balanced nitrogen fertilization. In conclusion, WFC demonstrates a scalable pathway toward more resilient and climate-smart food systems.

**ABSTRACT**

Soil acidification in China's croplands, driven by intensive agriculture, threatens both agricultural sustainability and ecological security. However, its large-scale spatiotemporal dynamics and underlying drivers remain poorly understood. We developed a meta model coupling of process model and machine-learning, integrating national soil survey information from the Chinese Soil Series Records and the VSD+ model to simulate and map soil pH trajectories from 1980 to 2100. We found a pronounced national acidification trend from 1980 to 2020, with average cropland soil pH declining by 0.37 units (from 7.05 to 6.68). This trend varied regionally, with the most severe acidification in Northeast China (ΔpH = -0.67) and the slowest decline on the Qinghai-Tibet Plateau (ΔpH = -0.11). Projections show that even under a nitrogen fertilizer zero-growth scenario, soil pH will continue to decrease to 6.49 by 2100. Our model reveals that fertilizer management exerts a stronger influence on acidification than climate change, as evidenced by minor differences among climate scenarios. Mechanistically, nitrogen transformation was the dominant acidifying process in upland systems, while both $HCO_3$ leaching and nitrogen transformation were primary drivers in paddy systems. This study provides a quantitative basis for sustainable nutrient management and offers valuable insights for mitigating soil acidification in global agricultural systems.

**ABSTRACT**

Microplastic pollution in agricultural soils threatens global food security by degrading soil health and reducing crop productivity. Despite continuous inputs from sources like plastic mulch and fertilizers, the global distribution and key drivers of this contamination are poorly understood. In this study, we synthesize a comprehensive global database of soil microplastic measurements. We integrate this database with key anthropogenic and environmental predictors in a knowledge-guided machine learning model to generate the first high-resolution global map of soil microplastic contamination, and identify its dominant drivers. This map identifies critical high-risk regions, providing a scientific foundation for targeted ecological risk assessment and sustainable soil management.

# Assessing human activity impacts on soil nutrient condition in Australia.

**Ho Jun Jang[1]*, Quentin Styc[1], Peipei Xue[1], Budiman Minasny[1], Alex McBratney[1]**

[1] *School of Life and Environmental Sciences, The University of Sydney, Sydney, Australia*

*hojun.jang@sydney.edu.au

**ABSTRACT**

Human activities, particularly intensive agriculture over the past 200 years in Australia, have significantly impacted soil properties due to European settlement. These impacts are especially evident in key soil nutrients such as soil organic carbon (SOC), nitrogen (N), phosphorus (P), and potassium (K). However, there is still a lack of robust approaches to quantify how soil nutrients have changed under human influence over the continent.

In this study, soil samples were collected across Australia in regions receiving between 500 and 600 mm of rainfall, as these areas are more likely to experience agricultural activity. Sampling points were spaced approximately 100 km apart. At each location, representative soils, identified using pedogenon mapping, were collected from both native vegetation and intensively managed agricultural land within a 30 km buffer.

A total of 273 soil samples were collected and analysed. We compare soil pH and nutrient levels (SOC, N, P, and K) across different land uses and major pedoclimatic regions (eastern, western, and central Australia). We show SOC levels in agricultural areas were lowered than in natural vegetation areas due to soil disturbance and reduced organic inputs. However, fertiliser application in agricultural lands results in elevated concentrations of other nutrients and soil pH. By quantifying these differences, we aim to evaluate how much soils have changed due to human activities and provide farmers with practical recommendations for improving land management and supporting long-term soil security.

# WoSIS: An international effort to share standardised soil data for the world

**Luis Pisco Calisto [1*], Jiarong Li [1], Divya Pandey [1], Laura Poggio[1], Niels H. Batjes [1]**

*[1] ISRIC-World Soil Information, Droevendaalsesteeg 3, Building 101, 6708 PB Wageningen, the Netherlands*

Luis.calisto@isric.org

**ABSTRACT**

WoSIS is a Soil Information System composed of a large soil database; application programming interfaces (API); workflows; dashboards and more. It is developed and maintained by ISRIC with the aim to: safeguard world soil profile data; quality-assess and harmonise/standardise the data; and subsequently serve the shared data to support digital soil mapping and a range of environmental applications.

WoSIS provides a growing number and range of quality-assessed and standardised soil profile data for the world. The system draws on voluntary contributions from numerous data holders/providers worldwide who are willing, and able, to share their data for the greater benefit of the international community. In return, the data providers will get the following for their datasets: a dashboard with various summaries of the contents of the datasets, links to download the datasets in a variety of formats and standards, and if required a DOI to facilitate findability and citeability. A thorough (mostly automated) standardization and harmonization process improves the consistency/comparability of the ingested data; source data quality, however, remains the responsibility of the data provider.

WoSIS data ingestion follows a strict protocol integrating reproducible programmatic data cleaning, ETL (extract, transform and load) rules to harmonize and standardise data using a GraphQL API. The

ETL workflow validates, harmonises, and structures contributed datasets in accordance with WoSIS data model based on the ISO 28258 standard. Submitted soil profile data undergo automated structural checks such as detection of overlapping horizons, implausible values, unit inconsistencies, and vocabulary mismatches. WoSIS never alters the original data. Instead, during data entry, the system flags potential issues for the contributor, who remains responsible for resolving them by either correcting the data or removing the affected records before re-submission; only ‘error free’ datasets can enter WoSIS.

The ETL pipeline is powered by a schema-guided GraphQL API that allows users to upload and check/refine their own datasets, while the ISRIC WoSIS team can perform the ingestion on behalf of providers using the same procedures, in particular for large datasets.

In this presentation we are going to discuss the principles of WoSIS data ingestion and illustrate the latest developments for the API for checking, querying and uploading soil datasets into WoSIS itself, for further distribution to the international community.

# Low-Cost Sensors for Monitoring Soil Condition in Landscape Restoration

**Maille Todd[1], A.J.E. Gallant[1], A Wang[2], J Plucinski[2] & V.N.L. Wong[1]***

[1] *School of Earth, Atmosphere and Environment, Monash University, Wellington Rd, Clayton VIC 3800 Australia*

[2] *Freaklabs, Montrose, Victoria, Australia*

*vanessa.wong@monash.edu

**ABSTRACT**

Soil is not consistently monitored despite its critical role in ecological function. One of the primary barriers to widespread soil monitoring is cost, which limits the ability to collect long-term, spatially distributed data. To address this gap, we deployed low-cost wireless soil moisture (AUD 60) and temperature (AUD 5) sensors at a site undergoing rehabilitation. The project aims to improve soil moisture retention through management interventions such as netting and wooden stakes to facilitate landscape revegetation.

Twenty-seven sensor stations were installed across an area of 2.81 km2, with each station including two soil moisture sensors installed at depths of 5 cm and 30 cm and soil temperature, pH and electrical conductivity (EC) sensors installed at a depth of 5cm. The soil moisture sensors have responded consistently to rainfall, drying events, and diurnal temperature and transpiration cycles over the first five months of operation. These responses aligned with event magnitude (i.e. larger rainfall events produced larger moisture changes), indicating efficacy in data monitoring from these low-cost sensors on these time scales.

The region was also progressing into drought during this time, which provides crucial data of landscape responses during hydrological extremes. On average, control sites (with higher vegetation cover) reported higher surface soil moisture (5 cm) than rehabilitated sites, likely due to natural differences in site conditions. At 30 cm depth, moisture readings were more comparable across sites. Surprisingly, scalded sites exhibited elevated soil moisture at both depths. This may be attributed to their proximity to a gully, where runoff accumulates. However, a more plausible explanation is that soil disturbance during sensor installation resulted in looser soil, temporarily increasing infiltration rates. These findings highlight the promise of low-cost sensors as scalable tools for enhancing soil monitoring in restoration contexts, particularly during periods that are subject to environmental stress such as drought and their impacts on the sub-surface

# Using legacy data and geostatistics for assessing soil organic change in the Sele River Plain (southern Italy)

**Buttafuoco G.[1*], Rao M.A.[2], Perreca C.[2], Vingiani S.[2]**

[1] *National Research Council of Italy, Institute for Agricultural and Forest Systems in the Mediterranean, Rende CS. Italy*
[2] *University of Naples Federico II, Department of Agricultural Sciences, Portici NA, Italy*
*gabriele.buttafuoco@cnr.it

**ABSTRACT**

The recent approval by the European Parliament of the Soil Monitoring Law is a major step forward monitoring and assessing EU soils in the perspective of the path to healthy soils. Legacy datasets of soil properties, such as soil organic carbon (SOC), represent valuable resources for establishing SOC baseline and for assessing changes in SOC when multiple datasets from different time periods are available. In this study two SOC datasets (2003 and 2016/17) were analyzed to establish a baseline and to assess SOC changes in the Sele Plain (southern Italy). This area is characterized by intensive horticulture, with ready-to-eat leafy vegetables, representing a major economic driver. Decline in soil fertility resulting from such intensive practices remains a critical concern. The datasets were generated using different sampling designs with no resampling involved. Following preliminary checks, soil samples within the study area were selected from the two datasets (129 for 2003 and 168 for 2016/17). A statistical and spatial analysis was carried out as first analysis and different geostatistical methods were applied to analyze and understand spatial and temporal variation of SOC. After a univariate structural analysis, omnidirectional spherical models of variograms were fitted for both SOC2003 and SOC2016/17. Then, 200 realizations were simulated using turning bands simulation (TBS) to better visualize heterogeneity and assess uncertainty for both datasets. From the simulated SOC values for each pixel of the simulation grid, maps of 'expected' values at any location and the related standard deviations were obtained. The standard deviation provided a measure of uncertainty on the 'true value' of SOC. The SOC difference map between SOC2003 and SOC2016/17 enabled to visualize the spatial pattern of changes. To account for the different soil sampling designs, polygon kriging was used to estimate SOC values across soil unit polygons. Polygon kriging provides estimates of the expected value for each polygon along with a standard deviation. Within a Gaussian framework, the latter was used to calculate confidence intervals and to test whether the expected values for each soil unit in 2003 and 2016/17 were statistically different. To interpret temporal changes in SOC, a geostatistical tool known as pseudo cross variogram was applied. This method is used when two variables (in this case, SOC in 2003 and 2016/17) are measured at different locations, and it estimates spatial correlation by pairing nearby points from the two datasets. The pseudo cross variogram results revealed heterogeneous spatial variability: some areas exhibited marked changes, whereas others remained relatively stable. Direct variograms revealed higher SOC spatial variability in 2016/17 than in 2003, likely due to management or vegetation changes. The variogram of the SOC difference (2016/17 minus 2003) increased with distance, suggesting a coherent spatial pattern rather than random noise.

# Quantifying Pan-European Soil Organic Carbon Trends and Associated Uncertainty for Soil Health Monitoring

**Ali Sakhaee[1]*, and Florian Schneider[1]**

[1] *Thünen Institute of Climate-Smart Agriculture, 38116 Braunschweig, Germany*

*a.sakhaee@thuenen.de

**ABSTRACT**

Soil organic carbon (SOC) is one of the key soil health indicators and thus a central property for large-scale soil monitoring and reporting. However, quantifying SOC change across large spatial and temporal scales remains challenging due to heterogeneous data sources, scale effects, and uncertainty inherent in predictions derived from machine learning models. Robust and transparent analytical frameworks for estimating SOC change are therefore required to support reliable soil health monitoring and informed decision-making.

In this study, we present pan-European spatial estimates of SOC trends in agricultural and forest land uses. We used harmonized spatio-temporal SOC predictions for the period 2000–2021, derived from machine-learning models that integrate soil observations from various European soil inventories together with satellite-derived products and other environmental covariates. Pixel-wise SOC trends were estimated at 30 m spatial resolution using linear regression models, and trend uncertainty was quantified using upper and lower bounds of prediction intervals. To enhance interpretability for soil monitoring applications, we further developed a spatial agreement metric that identifies areas where the direction of SOC change is consistent across uncertainty bounds, thereby delineating regions with robust trend signals.

Our results reveal pronounced regional contrasts in SOC trends across Europe. SOC declines are observed in many regions of eastern Europe and in parts of western and northwestern Europe, including the United Kingdom, whereas large areas of central Europe exhibit relatively stable SOC levels. In contrast, parts of northern Europe, such as Sweden, show increasing SOC trends. These spatial patterns likely reflect interactions between climate conditions, land-use history, and long-term management practices.

Maps of uncertainty and agreement demonstrate substantial spatial variability in the reliability of SOC trend estimates. Northern regions, such as Norway, generally exhibit higher uncertainty, while countries such as France and Germany show comparatively low uncertainty, highlighting spatial differences in the confidence of SOC trend estimates for soil health monitoring.

This work demonstrates how integrating soil data, spatial modelling, machine learning, and uncertainty analysis supports large-scale, transparent monitoring of soil health indicators beyond static soil property maps, contributing to scalable soil monitoring and soil carbon reporting initiatives.

# Modeling of spatiotemporal heterogeneity of agrochemical properties of soils within the territory of testing agricultural crop varieties

**Sakhabiev I.A.*, Bodalev K.A.**

*Kazan Federal University (Institute of Ecology, Biotechnology and Nature Management, Kazan, Russia)*
*E-mail IlnASahabiev@kpfu.ru

**ABSTRACT**

The paper considers the problem of assessing and modeling the spatial and temporal heterogeneity of key agrochemical properties of the soil (hydrolyzable forms of nitrogen, mobile forms of phosphorus and potassium) in the territory of the variety testing site (80 ha) of the Republic of Tatarstan (Russia). The heterogeneity of soil indicators is a significant source of errors in assessing the productivity and adaptive potential of new varieties and hybrids, which can lead to biased conclusions and slow down breeding progress. Based on data from a detailed agrochemical survey and long-term monitoring of the site's soils (1987-2025), the spatial and temporal heterogeneity of agrochemical properties of soils was modeled using a digital soil mapping approach based on machine learning methods (random forest). The spectral indices of the Landsat 5/8 satellites of open and vegetation-covered soil, as well as the morphometric attributes of the SRTM digital relief model, were used as predictors of the heterogeneity of soil indicators. Spectral indexes for different years were calculated based on the Google Earth Engine service. The NDVI, SAVI, BSI, and NBR2 spectral indexes, as well as individual bands of Landsat 5/8 satellites, were used as dynamic indexes. The estimation of modeling uncertainty was carried out using the quantile regression forest (QRF) approach using the PICP prediction interval coverage probability indicator (PICP). It is shown that from 1987 to 2025, the site is heterogeneous in the content of nutrients. The coefficient of variation of soil properties varies significantly: for hydrolyzable nitrogen from 25% to 13%, for mobile forms of phosphorus and potassium from 25% to 32%. Based on the modeling results, it was revealed that using random forest models, depending on the year of observation, it was possible to describe 53-78% of the spatial heterogeneity of the content of hydrolyzable nitrogen, 66-76% of the heterogeneity of mobile phosphorus and 55-72% of mobile potassium. According to the analysis of Shapley numbers, the relative contribution of predictors to the spatial distribution of agrochemical properties is unstable: in some years, the spatial distribution of indicators is better described by remote sensing data, in others by terrain characteristics. Based on the results of the work, recommendations are proposed for optimizing the planning of field experiments, stratification of plots and adjustment of yield results taking into account the identified soil trends.

## ABSTRACT

Soil erosion, a critical environmental challenge, is exacerbated by factors such as intense rainfall, strong winds, and flowing water, leading to the formation of gullies. Among these, ephemeral gullies (EGs), characterized by their transient nature and formation due to concentrated overland flow, present unique challenges in soil conservation. Despite their significant impact on soil degradation, EGs have been relatively understudied, primarily due to their temporary existence and the limitations of existing measurement techniques. Addressing this gap, our study introduces a novel, cost-effective approach for the quantification and analysis of EGs. We have developed a Pin-artboard tool (Gulliometer), specifically designed for capturing the morphology of EGs in a field setting. Complementing this tool, we employed an advanced image-processing technique to accurately quantify the cross-sectional area of EGs with minimal error. This technique enables the calculation of EG volume by integrating cross-sectional profiles obtained at closely spaced intervals. Our methodology offers a significant improvement over traditional modeling approaches and field-based methods, which are often constrained by extensive data requirements, high costs, and limited applicability in varying field conditions. The Gulliometer, combined with our image-processing technique, provides a reliable, efficient, and accessible means of studying EGs, thereby contributing valuable insights into soil erosion dynamics. This approach not only enhances our understanding of ephemeral gully erosion but also aids in the development of effective soil conservation strategies and informed decision-making in land management.

## ABSTRACT

The European Commission recently adopted the 'Soil Monitoring Law', aimed to establish a soil monitoring framework to maintain EU soils in a healthy condition and to prevent and address all aspects of soil degradation, with a view to achieving healthy soils by 2050 (November 2025). Soil geospatial data also fall under the remit of the INSPIRE Directive (2007), aimed to establish an infrastructure for spatial information in Europe to support Community environmental policies. While the default encoding of INSPIRE Soil data is XML based GML, INSPIRE officially endorsed GeoPackage encoding rules as a Good Practice (November 2022), enabling the GeoPackage format to be used as an additional or alternative to the GML format. The European Joint Programme Soil (EJP SOIL) horizon 2020 research project, with the aim to streamline the transcoding and harmonization of national agricultural soil datasets towards INSPIRE-compliant sharing, developed a "Software framework for a shared agricultural soil information system", published on GitHub. The framework builds on three pillars: a streamlined soil database encoded in GeoPackage format, robust data transformation pipelines, and semantic harmonisation with managed code lists. In line with INSPIRE Good Practices, a logical GeoPackage model for the INSPIRE Soil theme was derived from the INSPIRE conceptual model, implemented and validated for INSPIRE-compliance. The INSPIRE-SOIL Geopackage was accompanied by executable transformation rules and templates, to ensure technical compliance and usability inside GIS environments. Building on these foundations, the Horizon Europe project SoilWise, aimed at providing an integrated and actionable access point to scattered and heterogeneous soil data and knowledge in Europe, is producing a revised version of the INSPIRE-SOIL Geopackage. A key novelty is the extension of the INSPIRE-SOIL Geopackage to align with the OGC SensorThings API 2.0 (STA2), enabling simple transfer between these formats. Specifically, STA2 defines ageospatial-enabled, RESTful data model and HTTP/MQTT bindings for creating, querying, and streaming observations consistent with the OGC/ISO Observations, and Measurements concepts, thereby strengthening near-real-time interoperability for soil monitoring networks and services.

Overall, the combined approach — INSPIRE-aligned GeoPackage encoding for structured soil datasets and STA2-based services for observational time-series — delivers a practical and future-proof pathway to interoperable soil information, therefore, contributing to FAIR principles. It is aimed at reducing provider burden, improving consumer usability, and bridging static and dynamic data flows in support of EU soil policies and the recently adopted Soil Monitoring Law.

# Step towards a 1:100,000-scale Soil Map of Italy supporting the implementation of a national soil monitoring network and service

**G. L'Abate* , S. Mocali, R. Napoli, M. Fantappiè, C. Piccini, S. Pellegrini, N. Vignozzi, R. Pastorelli, G. Valboa, L. D'Avino, R. Barbetti, G. Moretti, M. Finoia, A. Lachi, A. Orlandini, F. Rocchi, E. Tondini, C. Lozano Fondon, G. Corti**

*CREA (Research Centre for Agriculture and Environment, CREA, Florence, Italy)*

*giovanni.labate@crea.gov.it

**ABSTRACT**

CREA, with the support of "Ministero dell'agricoltura, della sovranità alimentare e delle foreste" (MASAF), has been collaborating for years on the production of soil maps for Italy. The first printed version is dated 2012 (scale 1:1,000,000), and updated the previous one from 1966, in terms of both knowledge and methodologies.

On charge of "Ministero dell'Ambiente e della Sicurezza Energetica (MASE)", is to set in place an Integrated Monitoring System (SIM). MASE-SIM is a long-term surveillance/monitoring system to implement preventive measures for scheduled maintenance of the territory, optimizing the use of resources, and managing emergencies. This realizes, by others, goals of EU-wide framework for assessing and monitoring soils established by the Soil monitoring law (UE 2360/2025). The production of the Italian soils map at 1:100,000 scale is one of this framework application goals, the Precision Agriculture.

Map development requires the integration of information: cartographic and digital maps, collected soil observations through national, regional campaigns,or research institutions.

A new soil profiles survey campaign (n=1500) started on spring 2025 with the dual objective of intensifying spatial information (n=1350) and updating part of the previous data (n=150 out of about 27000), introduced by a training school for surveyors. The References manual for nationally harmonized soil survey (Costantini, 2008). was updated and a dedicated Soil survey App & Management portal was developed, with CREA support. This last was aligned to the "Software framework for a shared agricultural soil information system", produced within H2020 EJPSOIL Joint European Research Program, conforming soil data to the INSPIRE Directive (2007/2/EC).

These coordinated efforts aim to establish a harmonized national soil information system, of which the Italian soils map represents a key deliverable and will represent the spatial distribution of the main observed soils in the national territory.

**Acknowledgments**

Authors Acknowledge Ministero dell'agricoltura, della sovranità alimentare e delle foreste (MASAF) for founding of the work, Ministero dell'Ambiente e della Sicurezza Energetica (MASE) for the leading activity on setting the Integrated Monitoring System (MASE-SIM).

**ABSTRACT**

Cropland quality underpins food security and sustainable agriculture. However, existing monitoring networks lack systematic design, resulting in sampling redundancy, insufficient spatial coverage, and an urgent need for optimization. The proposed research focuses on the optimization strategies for cropland quality monitoring networks. Drawing on the framework of LUCAS-Copernicus, this research integrates existing monitoring networks with crowdsourced survey data. Multi-source remote sensing features further characterize sampling point attributes within a multidimensional feature space. Spatial statistical methods—including joint probability density distribution analysis, bin-based selection, and composite indicator evaluation—are applied to quantitatively assess the representativeness of candidate sampling points and to perform stratified selection. Ultimately, we refine the optimized network by considering monitoring priority levels and spatial distance constraints, incorporating field validation results to enhance robustness.

Participation in this conference will facilitate knowledge exchange among researchers, practitioners, and policymakers, fostering interdisciplinary collaboration in cropland quality monitoring. In addition, the integration of thematic baseline datasets, such as soil salinity maps, together with specialized monitoring networks constructed through sample size estimation and stratified sampling, demonstrates the scalability and adaptability of the proposed approach for addressing specific cropland quality issues. The anticipated outcomes are expected to support governmental agencies in optimizing cropland quality monitoring networks, thereby enhancing monitoring capacity, improving cropland management, and advancing understanding of cropland quality dynamics. This ABSTRACT is submitted with the objective of stimulating academic discussion and promoting sustainable land management.Thank you for considering this contribution.

# Spatio-temporal patterns and environmental controls of soil organic carbon stocks in global tidal wetlands since 2009

## ABSTRACT

Tidal wetlands are important blue carbon sinks and a global research priority for climate mitigation due to their high carbon storage. While current global estimates of tidal wetland soil organic carbon (SOC) stocks mainly focus on individual wetland types and calculate changes based on wetland area changes, comprehensive assessments of SOC stocks across tidal wetland types and their dynamics remain scarce. By jointly accounting for spatio-temporal changes in both SOC density and wetland extent, this study provides the first spatially explicit and temporally resolved global assessment of SOC stocks and decadal changes across major tidal wetland types: mangroves, salt marshes, and tidal flats. Using a spatio-temporal digital soil mapping (ST-DSM) framework, we integrated global soil observations (5,489 locations, 42,154 soil layer records) with 62 environmental covariates to generate 90 m SOC maps at three depth intervals (0 ~ 30 cm, 30 ~ 60 cm, and 60 ~ 100 cm) for two time periods (2009-2014 and 2015-2020). Results reveal a global SOC decline from 8.80 (±0.09) Pg to 8.26 (±0.09) Pg (-6.1%), with greater losses in deeper layers. Low-latitude regions such as southern Asia and Africa were key loss hotspots. Mangroves showed the largest losses, mainly driven by decrease in SOC density. Tidal flats lost both SOC density and area, whereas salt marshes exhibited moderate gains caused by area expansion and SOC density increase. SOC losses were more pronounced in countries at lower-middle and upper-middle income levels. Driver analysis indicated that oceanographic and climatic factors were the dominant controls on SOC dynamics, although the key drivers for the three wetland types differed. Quantifying spatial and temporal variability of SOC at a global scale, this work reveals the magnitude and drivers of blue carbon change and underscores the need for targeted wetland conservation to support sustainable management and climate mitigation.

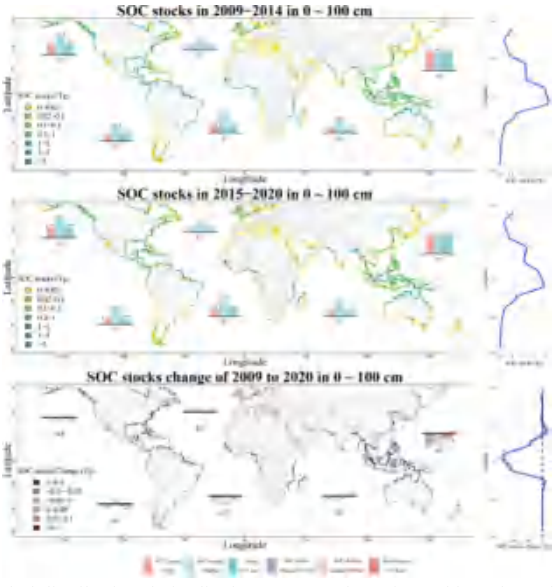

Fig 1 Aggregated per 0.5° cell results of global distribution, latitudinal patterns, and continental bar plots of soil organic carbon (SOC) stocks and their changes from 2009 to 2020 (0 ~ 100 cm soil depth). The bar graph shows the SOC stocks (Pg), SOC density (Mg/ha), and wetland area (103 km2) of each continent and their change.

# Estimation of Salinization in the Yellow River Delta Based on BO-XGBoost and a Four-Dimensional Feature Space, with Spatiotemporal and Trade-off/Synergy Factor Analysis

**Yang Jicun[1], Guo Bing[1,*], Yuan Xingming[2], Han Baomin[1] and Peng Jianbin[2]**

## ABSTRACT

Compared to traditional two- or three-dimensional feature spaces, a four-dimensional feature space can comprehensively account for the complex, coupled effects of multiple environmental variables on the formation and evolution of salinization—a approach that, to our knowledge, has not been previously reported. This study, focusing on the Yellow River Delta, constructed a total of 34 indices derived from Landsat 4/5/7/8/9 data, categorized into four types: salinity, water, vegetation, and others. The Bayesian-optimized XGBoost (Extreme Gradient Boosting) model was employed to screen for the optimal representative indices. Subsequently, an optimal salinization estimation model was developed based on the selected four-dimensional feature space. Using the gravity center model, the optimal parameter-based geographical detector model, and trade-off/synergy analysis, we analyzed and explored the spatiotemporal evolution patterns of salinization and its dominant influencing factors in the Yellow River Delta from 1985 to 2024. The main results indicate that:(1) The Bayesian-optimized XGBoost model effectively screened the indices, identifying SI1, SI, DVI, EVI, NEW, WI2019, COSR, and WET as the most suitable indices for characterizing salinization. (2) The four-dimensional feature space model (SI1-DVI-WI2019-COSR) achieved a high accuracy ($R^2$ = 0.916), demonstrating strong applicability for estimating salinization in the Yellow River Delta. (3) Spatial heterogeneity was observed across different salinization grades. Slightly salinized land accounted for the largest area (48.1%), while moderately salinized land accounted for the smallest (approximately 12.3%). Coastal areas exhibited more severe salinization. From 1985 to 2024, the annual mean salinization index showed a fluctuating downward trend over time. (4) The overall trend of salinization grade change was one of improvement. The most significant improvement occurred between 2005 and 2015, with an improved area of 36.33%. (5) The trade-offs and synergies among factors varied across different periods. The areal proportion exhibiting synergistic relationships between GDP, precipitation, DEM, and soil salinity generally showed an increasing trend, whereas the areal proportion showing trade-off relationships between these factors (GDP, precipitation, DEM) and soil salinity exhibited a decreasing trend.

# Interpretable salinization estimation model for Dongying City based on integrated multi-dimensional spectral indices with XGBoost-driven transformations

**ABSTRACT**

Against the backdrop of intensifying global climate change and anthropogenic activities, soil salinization is becoming increasingly severe, posing a significant threat to agricultural production and sustainable development. This study collected sample data from Dongying City, Shandong Province as the research area, focusing on investigating the effectiveness of combining mixed-scale transformations and high dimensional spectral indices in model inversion. The research process involved spectral transformations, upon which hybrid transformations were constructed. Subsequently, sensitive spectral bands were identified, leading to the development of two-dimensional and three-dimensional spectral indices. These indices served as feature variables to construct three types of models: Extreme Gradient Boosting (XGBoost), Partial Least Squares Regression (PLSR), and Convolutional Neural Network (CNN). The optimal model was evaluated using SHAP interpretability analysis. The results demonstrate that the proposed processing methods effectively enhance band sensitivity, improve model accuracy and generalization capability. Index operations conducted across different spectral bands can enhance spectral sensitivity characteristics or suppress the influence of noise to some extent. The outcomes provide a theoretical framework for optimizing spectral indices. The analysis reveals the salt-response mechanisms and noise resistance differences among various indices, facilitating the advancement of salinization monitoring towards greater precision, intelligence, and cost-effectiveness.

**ABSTRACT**

Against the backdrop of intensifying global climate change, soil salinization has become increasingly prominent, posing serious constraints to the sustainable development of agroecosystems. Compared with two-dimensional feature space, three-dimensional (3D) feature space can integrate the influences of three environmental variables, yet related studies remain scarce. This research selected the Yellow River Delta as the study area. Based on Sentinel-2 imagery and utilizing its unique red-edge bands sensitive to vegetation, we constructed 24 spectral indices across three categories: vegetation indices, salinity indices, and other indices. Feature selection was performed using a Bayesian-optimized XGBoost model. On this basis, multiple 3D feature spaces were constructed, and the optimal 3D feature space was selected by evaluating regression coefficients between in-situ measurements and the feature space combinations. Subsequently, soil salinization in the Yellow River Delta was inverted. The results indicate that: (1) among vegetation and salinity indices, NDRE and SI5 were identified as the most important features; (2) among the 3D feature spaces, the NDRE–Albedo–SI7 combination achieved the highest accuracy ($R^2$ = 0.921), demonstrating good regional adaptability, while the ERVI–SI7–Albedo combination performed the worst ($R^2$ = 0.453); (3) spatial inversion results show that lightly saline areas were most widespread (32% of total area), mainly distributed in the estuary region, whereas severely saline areas covered the smallest proportion (10%). This study provides theoretical support for monitoring and controlling soil salinization in the Yellow River Delta.

# Mapping and validating the root zone plant-available water holding capacity in central Ethiopia

**ABSTRACT**

Reliable maps of the root zone plant-available water holding capacity (RZ-PAWHC) are essential for assessing crop water availability and supporting climate-resilient agricultural planning. RZ-PAWHC is calculated by summing plant-available water holding capacity (PAWHC), adjusted for the soil fine earth fraction (SFEF), over the effective root zone depth (RZD). Existing Sub-Saharan Africa (SSA) maps of RZ-PAWHC rely on continental datasets and lack validation. We generated 100 m-resolution RZ-PAWHC maps for maize and wheat across central Ethiopia by integrating national soil datasets, digital soil mapping, pedotransfer function (PTF), and RZD derivation rules. Thirteen primary soil properties were mapped using Random Forest models, and two additional soil maps were obtained from Africa-SoilGrids. These were inputs to PTF to estimate volumetric moisture contents at field capacity and permanent wilting point, and to the RZD rules to determine RZD. A coarse fragment map was used to derive SFEF. RZD was defined as the shallowest of a restrictive soil layer, depth to bedrock, oxygen shortage, or a crop-specific maximum rooting depth. Prediction accuracy of the primary soil property maps ranged from a model efficiency of 0.17 for coarse fragments to 0.79 for pH-H2O. Derived maps showed substantial spatial variability in total PAWHC over 0–150 cm depth (122 ± 55 mm), with SFEF averaging 89%, and RZD (124 ± 28 cm) primarily constrained by bedrock (covering 45% of the mapped area) and oxygen shortage (22%). RZ-PAWHC maps had mean values of 91 mm for maize and 83 mm for wheat, with the lowest values in poorly drained, clay-rich soils. Compared with SSA maps for maize, the generated maps indicated higher RZ-PAWHC due to higher PAWHC, higher SFEF, and deeper rooting, with fewer restrictive layers. Validation against independent observations showed that the generated maps outperformed SSA maps for volumetric moisture contents. Both maps tended to overpredict observed RZD, although SSA maps occasionally predicted extremely shallow roots. RZD mapping using measured instead of mapped soil properties showed no improvement for maize but substantial improvement for wheat, particularly from coarse fragments, depth to bedrock, and drainage class. For both crops, the dominant source of uncertainty was the crop-specific maximum rooting depth in the RZD rules. For PAWHC, uncertainty was primarily driven by PTF limitations, with bulk density also contributing. These findings highlight the need to refine crop-specific effective maximum rooting depth, calibrate PTFs, and improve soil property maps to produce reliable RZD and RZ-PAWHC maps for crop modeling and agricultural planning in central Ethiopia.

**ABSTRACT**

Digital Soil mapping (DSM) at continental and global scale provides standardised global information layers. These layers can be useful to create soil information layers for areas for which local soil survey information is lacking. The recent availability of global and continental remote sensing-derived products coupled with the ease-of-access to computational resources has made the production of such layers, at increasingly higher resolution, easier. Therefore, it is ever more important to characterise and evaluate such DSM-derived products, in particular the type of actual information they can provide to users, that is, their fitness-for-intended-uses.

DSM studies commonly assess prediction uncertainty using various approaches, including multiple simulations or quantile random forests. These studies provide measures of accuracy derived from statistical (cross-)validation, often based on non-probability and non-representative observations. However, these accuracy metrics and uncertainty assessments do not encompass all the potential elements that could be used to characterise a DSM product, nor do they directly address user needs. In this study, we assessed maps based on area of applicability (i.e., the area in covariate space where the model learns about relationships based on the training data), the landscape heterogeneity both in the landscape itself and in covariate space, and the local influence of the covariates on the final products.

We present examples of continental and global mapping products, highlighting main accuracy, uncertainty and interpretability aspects and how these influence their suitability for intended use by stakeholders, decision makers and users in general at the given resolution. The results permit some practical reflections on how to integrate all the above elements to identify regions where the confidence in the predictions – for various intended uses -- is highest and the associated uncertainty lowest, and, conversely, where the product is not considered fit for use.

# Beyond uncertainties: making standalone metrics decision-oriented through game theory

**Trevan Flynn***

[1] *University of Fort Hare, Alice, South Africa*

*trevanflynn@gmail.com

**ABSTRACT**

Digital soil mapping and its associated uncertainties are communicated through accuracy metrics, confidence intervals, or taxonomic uncertainty maps that have limited relevance to end users. While these measures are essential for scientific transparency, they rarely translate into actionable information for decision-making. As a result, uncertainty often functions as an academic requirement for publication rather than a practical decision-support variable and is frequently overlooked outside specialist communities.

This disconnect reflects a broader limitation in digital soil mapping: uncertainty is typically treated as an endpoint rather than as information that can actively inform land-use choices. Here, we argue that uncertainty can be made functionally meaningful by reframing soil information within a game-theoretic decision framework. Game theory provides a well-established language for decision-making under incomplete information, where actors select strategies based on both expected outcomes and associated risks. Within this framework, soil maps are not static predictions, but information structures that shape rational decisions under uncertainty.

By jointly mapping spatial patterns, such as pedodiversity or other spatial patterns, and predictive uncertainty, soil information is transformed from a descriptive output into a strategic decision surface. In this representation, pedodiversity reflects the potential magnitude and diversity of ecosystem services, while uncertainty quantifies information asymmetry and risk associated with those potential outcomes. This bivariate mapping is formally analogous to a Bayesian game, in which land-use actors operate under incomplete information and ecosystem services act as spatially variable payoffs.

Distinct regions of this decision surface acquire clear interpretive meaning. Areas characterized by high pedodiversity and low uncertainty correspond to dominant or low-risk strategies, where ecosystem service potential is both high and reliable. In contrast, areas with high pedodiversity and high uncertainty represent high-reward but risk-sensitive options, where management actions may yield substantial benefits but also carry greater potential for unintended consequences. Regions of low pedodiversity indicate more limited strategic options, regardless of uncertainty. These distinctions are difficult to infer from spatial patterns or uncertainty maps alone but emerge naturally when combined.

By embedding uncertainty within a game-theoretic interpretation, digital soil mapping moves beyond accuracy-driven evaluation toward transparent, intuitive, and policy-relevant communication. This approach enables soil information to support rational, risk-aware land-use planning and governance, encouraging broader engagement with uncertainty as a guide for sustainable decision-making rather than as an isolated statistical metric.

## ABSTRACT

Operational Digital Soil Mapping (DSM) increasingly underpins land management, environmental policy and sustainability assessments. Yet its effective use is often constrained by outdated, heterogeneous or low functional relevance data. This study presents a reproducible and operational workflow to update and harmonise soil mapping in mainland Portugal at a 1:100,000 scale and using the WRB system, explicitly addressing the fitness for use of DSM products derived from legacy soil data.

Portugal provides a representative case where existing soil maps are inconsistent in classification systems (Soil Classification of Portugal vs. WRB), scales (1:25,000 vs. 1:100,000), and survey and mapping methodologies. In addition, the legacy 1:25,000-scale soil maps lack detailed characterizations for most soil units, and those that are characterized are often incomplete. Rather than relying on data-intensive predictive modelling, the proposed approach uses combinations of soil-forming factors (climate, lithology, and relief) to delineate homogeneous land units that frame and enable the reinterpretation of the 1:25,000-scale legacy soil maps. Within this framework, and considering three study areas (~300,000 ha each): (i) legacy soil profiles were compiled, validated, and harmonised; (ii) soil units were systematically converted to WRB References Soil Groups and qualifiers; (iii) provisional land units were refined to improve internal consistency; (iv) soil mapping units were operationally defined by identifying dominant, co-dominant, and associated soils in each refined land unit.

The resulting soil mapping units were quantitatively validated against 165 legacy soil profiles using a presence/absence scoring method, achieving 76–82% correspondence. This level of validation directly supports the fitness for use of the DSM products and strengthens their credibility for land management and planning applications. Results also demonstrate that lithology emerges as the primary driver of References Soil Group distribution under Mediterranean conditions, while relief and climate refine the spatial variability of key WRB qualifiers linked to soil depth, texture, cation exchange capacity, carbonates and soluble salts content, drainage conditions, water storage capacity, acidity and organic matter status. Despite being produced at a smaller scale, the updated and harmonised 1:100,000 soil map delivers more functionally relevant and interoperable soil information than legacy 1:25,000 maps.

The study explicitly highlights common DSM pitfalls—overreliance on sparse legacy data, opaque classification conversions, and limited validation—and demonstrates how a process-based and pedologically interpretable workflow can mitigate these risks. By prioritising operational robustness, reproducibility and clear validation over methodological novelty, this work provides a practical pathway for producing fit-for-purpose DSM products in data-scarce regions, supporting land evaluation, soil management and evidence-based decision-making at national and European scales.

**ABSTRACT**

As part of the Soil Monitoring and Resilience Directive, published on 12 November 2025, the EU parliament has emphasized the importance of setting measures for Union-wide harmonised monitoring and assessment of, and support for, soil health and soil resilience and tackling contaminated sites, in order to achieve healthy soils by 2050. Soil health is known as the continued capacity of soil to function as a vital living system within an ecosystem and land-use boundaries, sustaining biological productivity, maintaining or enhancing air and water quality, and promoting plant, animal, and human health *(Laishram et al., 2012)*. Recognizing this vital role, soil health has become a key parameter to assess, and several methods and tools have been developed for this purpose.

Among them, the MUSE method - originally a French acronym for *Method for the Evaluation of Soil Multifunctionality* - is a Digital Soil Mapping (DSM) approach that evaluates four soil ecological functions: carbon storage, biodiversity storage, infiltration capacity, and agronomic potential *(Branchu et al., 2021).* These functions are assessed individually and in combination through a scoring system that enables the spatialization of results and the evaluation of soil multifunctionality. The outputs of the MUSE method support the assessment of soil health and the guidance of soil management practices by promoting informed decision - making aimed at preserving soil functions, improving soil quality, and ensuring sustainable land-use practices.

The EU - funded Horizon Europe SPADES *(Spatial Planning and Design with Soil)* project aims to integrate soil health into spatial planning and design. By promoting soil literacy and gathering adaptable tools, methods and instruments among the countries involved in the project, SPADES is putting soil health at the heart of planning for the benefit of current and future generations.

Within the SPADES framework, this study seeks to advance the MUSE approach as both Digital Soil Mapping and a decision - support tool for soil health - inclusive land - use management and spatial planning on the European scale. To this end, the work evaluates the method's interoperability across diverse contexts, identifies and addresses barriers to its transposability, and tackles key challenges related to MUSE development and operationalization, including data availability, accuracy, reliability, practical usefulness, interpretability, and the scales "local versus global" transferability issue.

## ABSTRACT

Soil property mapping at the European scale currently relies on the Land Use/Cover Area (LUCAS) soil survey managed by the Joint Research Centre (JRC). Many Member States (MS) also maintain national soil information monitoring system (N-SIMS) that typically provide higher sampling densities. Technical issues such as harmonization of soil data points and covariates and legal issues such as constraints in sharing coordinates have hindered the integration of national soil information into Eu- wide mapping.
This study evaluates the influence of alternative digital soil mapping strategies on soil pH predictions, using different combinations of European-wide and national datasets in terms of both soil point observations and covariates. Predictive performance, spatial patterns, and cross-border coherence were assessed.
Six country-driven approaches were implemented independently by participating MS using the same modelling framework: (a) Eu-wide covariates (Eu Cov) with LUCAS data, (b) Eu Cov with N-SIMS, (c) Eu Cov with combined LUCAS and N-SIMS data (CombData), (d) Eu-wide and national covariates (Eu- Nat Cov) with LUCAS, (e) Eu- Nat Cov with N-SIMS, and (f) Eu- Nat Cov with CombData. In addition, two continental approaches were implemented by training a single model at the European scale using Eu-wide covariates with either (g) LUCAS data or (h) CombData (federated approach). The federated approach enables the incorporation of national point data without disclosing their coordinates, encompassing legal constraints.
Results indicate that, in most cases, the use of N-SIMS data improved model performance relative to LUCAS, as measured by RMSE, CCC, and MEC, with few exceptions.The use of CombData generally resulted in intermediate performance, often degrading the metrics achieved by N-SIMS alone. The inclusion of Nat Cov consistently enhanced model performance. Among continental approaches, the CombData model outperformed the LUCAS-only model across all evaluation metrics.
At the European scale, spatial patterns were broadly comparable; however, LUCAS-based maps tended to smooth extreme pH values captured by N-SIMS-based models. Substantial local discrepancies (up to 1.8 pH units) were observed between LUCAS and N-SIMS predictions, while N-SIMS and CombData maps showed high spatial consistency. Border artefacts were evident in all country-driven models but were fully eliminated in continental approaches.
Strengths and limitations of the tested approaches are discussed, highlighting the potential of integrating N-SIMS data into Eu-Scale mapping.

# National soil information grids of China: problems and possible solutions

**Feng Liu[1*], Ganlin Zhang[1]**

*[1]State Key Laboraory of Soil & Sustainable Agriculture, Institute of Soil Science, Chinese Academy of Science, Nanjing, China*

*E-mail Address: fliu@issas.ac.cn

**ABSTRACT**

Soil information has traditionally been presented as polygon maps at coarse scales. Solving global and local issues, including food security, water regulation, land degradation, and climate change requires higher quality, more consistent and detailed soil information. Accurate prediction of soil variation over large and complex areas with limited samples remains a challenge, which is especially significant for China due to its vast land area which contains the most diverse soil landscapes in the world. Based on almost 6000 soil profiles collected from a recent national soil survey and a suite of detailed environmental covariates, we integrated predictive soil mapping paradigm with adaptive depth function fitting, state-of-the-art ensemble machine learning and high-resolution soil-forming environment characterization in a high-performance parallel computing environment to generate 90 m resolution national gridded maps of soil types and basic soil properties (soil types, pH, organic carbon, sand, silt, clay, nitrogen, phosphorus, potassium, cation exchange capacity, bulk density, coarse fragments, thickness and colours) at multiple depths across China. Then, we used a set of pedotransfer functions and models to predict spatial variations of soil function (hydraulic, thermal, ecological, etc) properties. This study developed high resolution National Soil Information Grids of China as an alternative to the existing out-of-date, spatially-coarse national soil maps and also quantified spatial uncertainty of the digital soil information products which would be useful for decision-making. The relative importance of soil-forming factors in the predictions varied by specific soil property and depth, suggesting the complexity and non-stationarity of comprehensive multi-factor interactions in shaping soil spatial variations. More importantly, we highlighted the prolems and possible solutions in the soil informtion production and its applications under the conditions of limited samples in the large territory with complex soil landscapes. We also tried to describe the possible prospects can the third National Soil Survey can bring to the enhancement and applications of soil information grids of China.

**ABSTRACT**

Apparent soil thermal diffusivity between 5 and 10 cm can be estimated at the annual scale from temperature time series at two depths under one dimensional heat conduction [ 1,2]. However, purely statistical first harmonic fits may fail to capture atypical transient episodes, biasing parameter estimates and yielding physically inconsistent amplitude and phase relationships between depths. This work quantifies the impact of an explicit physical supervision and quality assurance scheme on national scale apparent diffusivity estimation in Uruguay. Daily soil temperature maps at 5 and 10 cm were used to build intra annual time series for each pixel and year, and the first annual harmonic was fitted by least squares, using a previously developed gridded soil temperature dataset [3]. A physical coherence domain (*Dphys*) for the harmonic parameter vector was defined by amplitude and phase constraints, and internal consistency metrics were formulated to quantify the mismatch between logarithmic amplitude attenuation and interdepth phase lag, including a symmetric relative discrepancy between diffusivity estimates. Global tolerance thresholds were derived through a Monte Carlo residual bootstrap based on paired daily residuals from in situ series, preserving the joint dependence between depths and filtering physically feasible realizations. Local intra annual flags based on vertical temperature differences and harmonic residuals were used to identify candidate segments for correction. For series showing locally incompatible behaviour, a subset based temporal filtering was applied to recover solutions within *Dphys* while minimizing the exclusion of observations and without forcing the remaining signal. Quality gains are assessed by comparing base and final fits in terms of the fraction of series within *Dphys*, the distributions of internal consistency metrics relative to thresholds, shifts in A, B, C quality classes, and the number of excluded observations. The results show that physical supervision increases feasibility and reduces internal inconsistencies while requiring limited removals for recoverable series.

This framework provides a transparent and scalable quality assurance strategy for generating annual and typical apparent diffusivity products from gridded soil temperature datasets.

**ABSTRACT**

Soil mapping is an effective method for obtaining the spatial distribution of soil properties, and conducting soil mapping across different periods can help identify dynamic changes in soils. Existing soil mapping studies have often been carried out at either small scales, such as the plot scale, or large scales, such as the regional and even global scale, while landscape-scale mapping has remained relatively less implemented. The landscape scale is crucial because it can effectively integrate multiple natural and anthropogenic driving factors, providing a key perspective for understanding soil property dynamics under complex interactions. In this study, landscape-scale mapping of topsoil total nitrogen (TN) in the typical temperate grassland of Xilingele was performed for 2014 and 2021 based on revisited sampling, in order to determine the spatio-temporal variation of TN and its dominant driving factors. The spatio-temporal variations of TN at 0–1 cm and 1–6 cm depths in a temperate grassland are identified to analyze the governing processes and identify the major contributing factors. The results showed that TN content exhibited a significant decreasing trend in the study area, with reductions of 0.043% at 0–1 cm and 0.012% at 1–6 cm depth. TN exhibited moderate spatial autocorrelation in both 2014 and 2021, and spatial variability increased at 1–6 cm as the nugget-to-sill ratio rose and range decreased. Higher elevations showed less TN loss than lower elevations, and leeward slopes experienced more substantial TN reduction than windward slopes. Higher land-use intensity correlated with more TN reduction, while long-term ungrazing or markedly reduced intensity lessened it. A wind erosion hotspot identified at a local peak showed less TN reduction, likely due to low land-use intensity and high vegetation cover at high altitude, which mitigated the impacts of wind erosion on TN variation. This study demonstrates that landscape-scale mapping can effectively detect the variation patterns and key drivers of TN. Such information is often overlooked at the field or regional scale. The approach thus enhances comprehensive understanding of the processes driving TN dynamics across the landscape and provides a reliable way to identify dynamic processes in soil-landscape systems.

**ABSTRACT**

When map users are confronted with a digital soil map (DSM), they do not recognize the traditional polygons delineating soil landscape segments. Rather, they see individual grid cell predictions, with no clear boundaries and often a fine pattern of predicted values. Further, DSM produces a separate map for each soil property at each depth slice. This is useful for modelers, but not for communicating with map users who conceive of, and use, soils as landscape elements recognizable as geomorphic or land use features. In this presentation, we discuss ways to extract meaningful landscape elements from DSM. One solution is to map soil classes, either from original training points or constructed from sets of soil property maps. These are holistic expressions of soil properties and functions and have long been used for communication with land users, especially for technology transfer. Further, soil classes are usually defined in relation to mappable landscape elements. These maps can then be aggregated into polygons at large scales or segmented into heterogenous associations of soil classes at smaller scales. Another solution is to aggregate (at large scale) or segment (at small scale) sets of properties at various depth slices into groups that are relatively homogeneous (aggregation) or with a defined pattern of heterogeneity (segments). These two methods should reveal landscape features that should be familiar to those who work with soil geography, for example landform facets and vegetation communities linked to soil types. This should make the DSM product more approachable and usable for these users. If the DSM products cannot reveal such features, that calls into question their quality and usefulness.

## ABSTRACT

Excess nutrient losses from agricultural fields have become one of the major drivers of freshwater eutrophication. Understanding the spatial distribution of soil nutrients is therefore essential for developing effective mitigation strategies. Digital Soil Mapping (DSM) provides a framework for quantifying soil variability by integrating environmental covariates, field observations, and numerical modeling techniques [1], offering an efficient way to predict soil nutrient dynamics in heterogeneous fields. The primary goal of this study is to apply the Digital Soil Assessment (DSA) approach, utilizing spatial soil information derived from DSM, to evaluate the effectiveness of buffer strips in capturing excess phosphorus (P) from agricultural runoff and to support their optimized design. Within the DSM framework, sampling points were selected using the conditioned Latin hypercube sampling (cLHS) method [2], which applies simulated annealing to capture real-world environmental combinations. Soil samples were collected and analyzed for available P using the Olsen P method. The SCORPAN model [3] was employed to compare regression, machine learning, and spatial statistical models in predicting soil available P distribution and to evaluate the influence of environmental covariates on model performance and interpretability, with a Random Forest (RF) model presented as an example illustrating soil available P prediction across the study area (Fig. 1). These analyses provided quantitative evidence for the effectiveness of buffer strips in mitigating soil phosphorus accumulation and runoff risk, serving as a scientific basis for optimizing buffer strip design and spatial configuration.

This study closely aligns with the conference theme by extracting knowledge from DSM and promoting DSA applications to support sustainable nutrient management and water quality protection, thereby encouraging farmers and policymakers to adopt these evidence-based practices in agricultural management.

## ABSTRACT

The foundation of ensuring national food security lies in cultivated land, with the core being its quality. The Northeast region, as China's most important commercial grain production base, has the sustainable utilization of its cultivated land resources and the guarantee of its production capacity directly related to the overall national food security strategy. However, under multiple pressures such as climate change, intensive utilization, and human management, the sustainability of cultivated land quality and grain production capacity in the Northeast faces severe challenges. Traditional cultivated land protection policies mostly focus on the "quantity red line," while research on the quantitative definition and realization pathways of the "quality red line" remains insufficient. In view of this, this study takes the entire Northeast region and its core grain production units (Heilongjiang Province, Jilin Province, Liaoning Province, and the Eastern Four Leagues of Inner Mongolia) as the research objects. Following the research logic of "evaluation - prediction - correlation - inversion - analysis," and comprehensively utilizing multi-source data and cutting-edge machine learning methods, it aims to scientifically delineate the cultivated land quality red line and key indicator red lines for the Northeast region, and reveal their multi-dimensional driving mechanisms, thereby providing a theoretical basis and decision support for implementing the "storing grain in the land" strategy and precisely improving cultivated land quality.

First, it systematically evaluated the cultivated land quality in the Northeast region and accurately assessed the grain production capacity. Based on the technical specifications for the third national soil survey's cultivated land quality grade evaluation, this study re-evaluated the cultivated land quality of the entire Northeast region and its respective provinces/leagues, obtaining detailed spatial distribution data of cultivated land quality grades. On this basis, to overcome the lag and limitations of traditional statistical data, we constructed a multi-factor integrated grain production capacity assessment and prediction model. The model integrates long-term time series historical yield statistics, high spatiotemporal resolution remote sensing images (such as vegetation indices, leaf area index, etc.), and gridded meteorological data (temperature, precipitation, etc.). Methodologically, we innovatively employed two single models with powerful nonlinear fitting capabilities—BP neural network and random forest—and further utilized an ensemble learning algorithm to combine their strengths, constructing a combined model with stronger robustness and higher prediction accuracy. This model not only enables accurate assessment of historical grain production capacity but, more importantly, allows for reliable prediction of future grain production capacity under different climate scenarios and farming management practices.

Second, it revealed the complex nonlinear relationship between cultivated land quality and grain production capacity. Clarifying the quantitative relationship between the cultivated land quality grade index and grain production capacity is the core scientific issue for delineating the quality red line. This study abandoned simple linear correlation assumptions and employed advanced machine learning interpretability techniques to deeply analyze this black-box relationship. Using the partial dependence analysis provided by the random forest model, we quantified the marginal effects of individual key cultivated land quality indicators (such as soil organic matter, pH, etc.) on grain production capacity, identifying the production capacity thresholds and inflection points for each indicator. Simultaneously, we introduced nonlinear activation functions such as the Sigmoid function from neural networks and successfully constructed a universal nonlinear relationship model from the comprehensive cultivated land quality grade index to grain production capacity. This model clearly delineates the pattern of "quality improvement - production capacity response": in low-quality grade intervals, a slight improvement in quality leads to a rapid increase in production capacity; whereas in high-quality grade intervals, the marginal production capacity benefit of quality inputs diminishes. The establishment of this relationship realizes the scientific transformation from "quality state" to "production capacity output," providing a key bridge for subsequently inferring quality requirements based on production capacity demand.

Third, based on multi-scenario simulations, it scientifically delineated the cultivated land quality red line for the Northeast region and its sub-regions. The delineation of the "red line" must be dynamically linked to future food demand. This study first predicted the future population size, dietary structure changes, and the resulting per capita grain demand in the study area. On this basis, different food security scenarios (e.g., basic subsistence, nutritional well-being, affluent abundance, etc.) were set, and the minimum total grain production capacity required to meet regional food self-sufficiency or specific commercial grain output tasks under each scenario was calculated. Then, we used the aforementioned established "quality-production capacity" nonlinear relationship model for reverse deduction: namely, targeting the guarantee of future grain production capacity demand under specific scenarios, we inverted the minimum cultivated land quality level that must be maintained in each region, i.e., the "cultivated land quality grade red line." Furthermore, based on the key indicator thresholds identified through partial dependence analysis, we further decomposed and transformed the comprehensive grade red line into specific key cultivated land quality indicator red lines (such as soil organic matter content red line, pH range red line, etc.). The research results not only provide a macro red line value for the entire Northeast region but also offer more refined, differentiated red line standards for regions with different physical geography and farming conditions, such as Heilongjiang Province, Jilin Province, Liaoning Province, and the Eastern Four Leagues of Inner Mongolia, achieving "tailored strategies for each location" and precise management and control for cultivated land quality protection.

*e-mail: marlianatri.widyastuti@sydney.edu.au

**ABSTRACT**

Accurate estimation of soil temperature (ST) dynamics is essential for understanding subsurface heat transfer and its influence on soil processes such as moisture retention, microbial activity, and carbon cycling. However, direct soil temperature measurements are often limited in space and time. This limitation limits the use of machine learning models to extrapolate in space. In this study, we solved the heat transfer equation numerically to estimate daily ST at multiple depths across Tasmania. Governed by soil moisture and soil physical and thermal properties (heat capacity and thermal conductivity), heat was propagated from the surface downward at 10 cm intervals to 1 m depth using a stable finite difference approach. Validation against in-situ observations from multiple sites showed strong agreement in capturing seasonal temperature fluctuations, with reduced error at deeper layers. Land surface temperature modelling using neural networks with land-cover further improved the model. This study demonstrates that finite difference combined with neural networks models can effectively characterize soil thermal regimes with minimal inputs, supporting dynamic soil temperature mapping and integration into process-based soil and carbon models.

# New dimensions of farmers' decision making: Demonstration of a 3D web-viewer for erosion mitigation strategies

**M. Melzer[1*], C. Cheng[1], and S. D. Bellingrath-Kimura[1]**

*[1] Leibniz Centre for Agricultural Landscape Research (ZALF), Müncheberg, Germany*

*marvin.melzer@zalf.de

**ABSTRACT**

Erosion mitigation strategies in agriculture are crucial for preserving soil functions, vital aquatic ecosystems and related ecosystem services. However, due to limited capacities among agricultural advisory services, farmers often do not receive adequate guidance. To address this gap, the Digital Agricultural Knowledge and Information System (DAKIS) aims to support farmers in planning and implementing mitigation strategies on individual sites. Within the project, digital and automated tools have been developed to calculate high resolution (1 meter) erosion rasters, erosion hotspots and potential sites for in-field raised vegetative barriers (beetle banks). This study examines: i) how to provide the given tools' results in a user-friendly format, ii) how to raise awareness of sub-field erosion risks, and iii) how to support farmers in implementing effective erosion mitigation strategies.

The study area is a watershed (ca. 15 km³) in southern Germany (Bavaria) characterized by a hilly topography and occasional heavy rainfall events leading to high erosion. The automated tools are applied, and the results are integrated into a public, web-based, 3D viewer (EROSPOT 3D). It allows for an interactive visualization and exploration of a three-dimensional landscape using a digital elevation model (Figure 1). Erosion risks are visualized using a traffic light color scheme ranging from low (green) to high (red), while delineated erosion hotspots are shown as clickable 3D objects (red) that provide quantitative information on annual soil loss. Potential sites for beetle banks are also shown as clickable 3D objects (green) that provide information about potential subsidies. The visualized 3D landscape is supplemented by a dataset showing runoff paths and water bodies (blue).

EROSPOT 3D illustrates the relationships between terrain, runoff, erosion, and connectivity to aquatic ecosystems while potential mitigation strategies are provided. Therefore, it reduces the need for physical meetings between advisors and farmers, as on-site knowledge, for instance about terrain characteristics and related runoff pathways, is provided online. Unlike 2D maps, terrain-based processes leading to erosion and the relevance of mitigation strategies, such as vegetation buffers along valley paths or beetle banks across slopes, are more comprehensible, which may improve farmers' understanding and acceptance of these strategies. Additional functions could be added to the 3D web-viewer, such as interfaces for downloading and transferring data, including spatial information on the position of beetle banks to enable exact on-site implementation as part of a holistic farm management information system for sustainable agriculture on sloping farmland.

**ABSTRACT**

Reliable and harmonized soil information remains scarce across Africa, limiting the continent's ability to address soil degradation, strengthen climate-resilient agriculture, and guide evidence-based land management. The Soils4Africa project implemented a coordinated, continental-scale field campaign across 33 countries to establish a standardized soil information baseline for agricultural lands. Using a hierarchical probabilistic sampling design, the campaign collected more than 25,000 soil samples and extensive field observations between 2022 and 2025, representing 80% of the planned coverage. Operational constraints, including restricted access to private estates, security risks, and severe seasonal flooding, prevented sampling in 21% of targeted locations, providing important lessons for future monitoring frameworks. Field observations revealed that African agricultural landscapes are overwhelmingly open, with more than half of sites exhibiting very sparse vegetation and 21% essentially bare. Tree canopy cover classes were dominated by the Absent and Scattered categories, indicating widespread structural simplification of agroecosystems. Soil physical and morphological properties exhibited high spatial variability, with coarse fragments, compaction, and subsoil rooting barriers commonly observed. Bulk density patterns further reflected regional differences in organic matter status, land use intensity, and parent material. Overall, the results demonstrate significant constraints to soil health linked to vegetation loss, limited fertility inputs, and inadequate soil and water conservation practices. The dataset and protocols developed through Soils4Africa provide a critical foundation for long-term soil monitoring, digital soil mapping, and sustainable land management planning across Africa.

**ABSTRACT**

Soil health can be assessed by the extent in which the soil is able to provide various ecosystem services. Ecosystem services are the direct and indirect contributions of an ecosystem to human well-being. The ecosystem services provided by soils or related to soils are known as soil-based ecosystem services (SESs). SESs are directly and quantifiably controlled by soil chemical, physical and biological properties, processes and functions. SESs do not occur separately in the environment, but simultaneously. They should thus be evaluated together as SESs bundles. In addition, these services are threatened by global changes, such as climate change and changes in land use, which will affect their provision. This work aims to define SESs bundles at the European Union (EU) level, and to evaluate the effect of climate and land use changes on their evolution by 2050. The SESs assessed include hydrological control (HC), soil erosion control (SEC), greenhouse gas and climate regulation (GHG), and primary biomass production (PBP). To assess HC, the digital soil mapping approach was used. SEC was quantified through the Revised Universal Soil Loss Equation (RUSLE). For GHG and PBP, dynamic global vegetation models (DGVMs) produced by UK Earth System Models (UKESM) were exploited. The impacts of climate change were assessed using two Shared Socioeconomic Pathways (SSP1-2.6: sustainable scenario, and SSP5-8.5: high-emission scenario with significant climate impacts). Concerning land use change, we used the projections provided by the LUISA (Land Use-based Integrated Sustainability Assessment) modelling platform. The assessment offers a comprehensive analysis of the spatial distribution and projections for the SESs bundles in the current state and by 2050. Clustering methods, specifically k-means, were employed to identify SESs bundles at EU scale. The proposed approach allowed us to identify hotspots with high or low provisions of a set of SESs and how these sets will be evolved by 2050 under the pressure of climate and land use change. Moreover, it could provide guidance for sustainable agriculture in the framework of the EU Green Deal and the Soil Strategy for 2050.

# Intelligent Mapping Paradigm to Overcome Systematic Bias in Remote Sensing SOC Estimation: A Case Study of the Black Soil Region in China and the United States

**Chong Luo[1*], Chao Wang[1], and Huanjun Liu[1]**

*1 Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun, 130102, China*

**ABSTRACT**

Soil organic carbon (SOC) is a crucial indicator for maintaining soil fertility and regulating carbon balance in black soil regions. However, its strong spatial heterogeneity and the limited capacity of remote sensing feature extraction often lead to systematic mapping errors, typically manifested as the underestimation of high values and overestimation of low values. To address this issue, we propose an SOC mapping framework that integrates prior geographic knowledge with deep learning, and develop a GMM-AG-CNNLSTM model incorporating fuzzy clustering and spatiotemporal feature extraction. The framework was applied to typical black soil regions in Northeast China and North America. A total of 2,616 surface SOC samples (0–20 cm) were compiled to build a multi-source spatiotemporal feature set. The approach first employs a Gaussian mixture model (GMM) to partition SOC levels and mitigate prediction bias caused by spatial heterogeneity. Subsequently, a weighted attention mechanism, convolutional neural networks (CNN), and long short-term memory (LSTM) networks are combined to achieve deep spatiotemporal feature fusion and generate SOC distribution maps at a 30 m resolution. Results demonstrate that the GMM-AG-CNNLSTM model achieved prediction accuracies of $R^2$=0.73/RMSE=5.42 g/kg in Northeast China and $R^2$=0.70/RMSE=5.89 g/kg in North America, outperforming random forest and conventional deep learning models, with greater stability in both high- and low-SOC regions. Spatial analysis further revealed that SOC in Northeast China exhibited higher mean values and a larger proportion of high-value areas compared with North America, though with a wider distribution of low-value areas. This study presents a high-accuracy SOC remote sensing mapping method that can provide valuable support for carbon sequestration assessment and degradation monitoring in black soil regions.

# Spatial Variability of Soil Acidity and Mapping of Selected Soil Properties in Chancho Micro Watershed, South western Ethiopia

Presenter: Dr. Abdissa Bekele Sima

Affiliation of Presenter: Oda Bultum University,Chiro, Ethiopia

Email: abdissabekele1@gmail.com / kenaabdi@gmail.com

Tel: +251913060939

**ABSTRACT**

The study was conducted to evaluate the spatial variability in soil acidity and mapping of selected soil properties in Chancho micro Watershed, Gechi District South Western Ethiopia. A total of 41 geo–Referencesd composite soil samples were collected from cultivated land using a random grid survey method at a depth of 20 cm for annual crops and 50 cm for perennial crops from surface soil of cultivated land. Selected soil property maps were developed using spatial prediction of semivariograms and the ordinary kriging interpolation technique using Arc-GIS.The pH of the soil was varied from extremely acidic (4.32) to strongly acidic (5.28). The values of exchangeable acidity and exchangeable aluminum were ranged from (0.26 to 2.3cmolckg-1and (0 to 1.87 cmolckg-1), respectively. Available phosphorus stretched from 0.45 to 1.88 mgkg-1, which is low to very low level whereas, optimum to low level organic carbon value that ranged from 1.06 to 3.93% was recorded. Furthermore, high to low levels of exchangeable calcium ranged from 13.12 to 5.05 cmolckg-1 was observed. The finding indicated that deficiency of available phosphorus, organic carbon, total nitrogen, and exchangeable calcium were the major limiting factors of acidic soil of study area. Thus, digital soil mapping produced for this study was important to address spatial variability of soil acidity and nutrient status in agricultural lands. Consequently, it is basic for efficient nutrient management, advisory work and decision makers to enhance site specific soil acidity management.

**ABSTRACT**

Cultivated lands play a crucial role in terrestrial carbon cycle, and enhancing soil organic carbon (SOC) sequestration in these areas can help effectively mitigate the rise of atmospheric $CO_2$ concentration. In this study, topsoil (0-20 cm) saturated SOC and its density of cultivated soil in Northeast China were mapped using a boosted regression trees (BRT) model. The distribution of the SOC sequestration potential was also calculated
based on the difference between saturated SOC and SOC density in ArcGIS. Nine environmental factors including climate, topography and lengths of cultivation data (LCD) and 197 soil samples are used. A 10-fold crossvalidation technique is applied to derive four statistical indices - mean absolute prediction error (MAE), root mean square error (RMSE), coefficient of determination ($R^2$) and Lin's consistent correlation coefficient (LCCC) to verify the model performance. The model explains 81% and 85% of the spatial variation of saturated SOC and SOC density, respectively. Mean annual temperature and mean annual precipitation are key factors controlling SOC density and saturated SOC distribution. In addition, LCD showed a similar spatial pattern to SOC sequestration potential, influencing the distribution of SOC density and saturated SOC in the study area. We recommend LCD as an important factor to consider in saturated SOC and SOC density predictions, especially in the farmland ecosystem with a long reclamation history. Accurate mapping SOC sequestration potential and identifying environmental factors will help manage land use and promote soil quality evaluation and improve soil carbon sequestration in this region.

**ABSTRACT**

Understanding the spatiotemporal distribution of soil organic carbon (SOC) stocks enables a critical assessment of terrestrial carbon sequestration potential and supports the formulation of effective climate mitigation policies.However, the prevailing emphasis on surface soil layers in SOC research has neglected the full three-dimensional distribution of stocks, its spatial heterogeneity, and the primary controls on subsurface carbon accumulation. Consequently, we developed a novel hybrid framework integrating equal-area spline functions, boosted regression trees (BRT), and a space-for-time substitution method. This approach was applied to quantify the vertical profile of SOC stocks in Tibet and project their dynamics under future climate warming scenarios. To this end, a dataset comprising 105 soil profiles and nine environmental covariates (climatic, topographic, and anthropogenic) was utilized to calibrate and validate the BRT model, which involved a 10-fold cross-validation procedure. The model exhibited robust predictive accuracy, with low MAE and RMSE alongside high $R^2$ and LCCC values. Spatially, SOC stocks were predicted to be highest in the southeast and lowest in the northwest, a pattern corresponding to grassland ecosystems storing the largest carbon pool. Over 47% of this pool was concentrated in the upper 30 cm. Projections under 1.5 °C, 2 °C, and 4 °C warming scenarios indicated total SOC stocks (0–1 m) would decrease by 0.43%, 0.60%, and 1.40%, respectively. The three-dimensional variability of SOC stocks was primarily controlled by mean annual precipitation, slope gradient, and slope aspect—insights that pave the way for high-resolution three-dimensional mapping under different climate scenarios and directly support the development of adaptive land management strategies for improved carbon governance.

**ABSTRACT**

Soil organic carbon (SOC), a critical component of the carbon pool in grassland ecosystems, playes a vital role in maintaining soil fertility, regulating carbon cycling, and responding to climate change. This study developed boosted regression tree (BRT) and random forest (RF) predictive models based on SOC data collected from 688 grassland sites across China in 2018, along with eight terrain and climate-related environmental variables. Through 10-fold cross-validation and evaluation using four performance metrics—R2, Lin's concordance correlation coefficient, mean absolute error, and root mean square error—the BRT model was found to outperform the RF model in terms of prediction accuracy and consistency, with significantly lower errors. The key environmental drivers influencing SOC distribution were identified as annual mean precipitation, elevation, and annual mean temperature. Based on these findings, the "space-for-time" substitution approach was applied, and the BRT model was used to project spatial changes in grassland SOC across China in the 2050s and 2090s under two future climate scenarios (SSP245 and SSP585). Results indicate that by the 2050s, SOC content is projected to decrease by 5.3 g kg-1 under the SSP245 scenario and by 5.8 g kg-1 under the SSP585 scenario compared to 2018 levels. By the 2090s, the decline under SSP245 is expected to reach 6.6 g kg-1, while under SSP585 it will reach 8.5 g kg-1. The high-resolution SOC content spatial data and projections generated in this study provide valuable scientific support for climate change adaptation strategies in China's grassland ecosystems, contributing to sustainable soil management and ecological restoration efforts..

**ABSTRACT**

Soil organic carbon (SOC) plays a critical role in the global carbon cycle and serves as a sensitive indicator of climate change impacts, with its dynamics significantly influencing regional ecological security and sustainable development. This study focuses on the Songnen Plain in Northeast China—a key black soil agricultural region increasingly affected by water erosion, primarily through surface runoff and rill formation on gently sloping cultivated land. We aim to investigate the spatiotemporal dynamics of SOC stocks across different cultivated land erosion zones under projected future climate change scenarios. To quantify current and future SOC stocks, we applied a boosted regression tree (BRT) model based on 130 topsoil samples (0–30cm) and eight environmental variables representing topographic and climatic conditions. The model demonstrated strong predictive performance through 10-fold cross-validation, yielding high $R^2$ and Lin's concordance correlation coefficient (LCCC) values, as well as low mean absolute error (MAE) and root mean square error (RMSE). Key drivers of SOC stock spatial variation were identified as mean annual temperature, elevation, and slope aspect. Using a space-for-time substitution approach, we projected SOC stocks under the SSP245 and SSP585 climate scenarios for the 2050s and 2090s. Results indicate a decline of 177.66 Tg C (SSP245) and 186.44 Tg C (SSP585) by the 2050s relative to 2023 levels. By the 2090s, SOC losses under SSP245 and SSP585 are projected to reach 2.84% and 1.41%, respectively, highlighting divergent carbon dynamics under varying emission pathways. Spatially, SOC stocks were predominantly located in areas of slight (67%) and light (22%) water erosion, underscoring the linkage between erosion intensity and carbon distribution. This study underscores the importance of incorporating both climate and anthropogenic influences in SOC assessments. The resulting high-resolution SOC distribution map provides a scientific basis for targeted ecological restoration, black soil conservation, and sustainable land management in the Songnen Plain, thereby supporting regional climate resilience and China's "dual carbon" goals. These insights also contribute to global efforts in enhancing soil carbon sequestration and achieving carbon neutrality goals.

# Digital mapping of Solonetz within forest-steppe landscapes of the Oka-Don Lowland

**Kornilov D.**[1*], **Kornilova A.**[1,2], **Lozbenev N.**[2]

[1] *Lomonosov Moscow State University, Moscow, 119999 Russia*

[2] *Dokuchaev Soil Science Institute, Moscow, 119017 Russia*

*korniloff.dania@mail.ru

**ABSTRACT**

Chernozems dominate the flat, poorly drained interfluves of the Oka-Don Lowland under conditions of shallow groundwater. The landscape is characterized by numerous shallow flat depressions, where Solonetzes develop due to a pulsating hydrological regime, saline parent materials, and mineralized groundwater close to the surface. This area represents one of the northernmost occurrences of Solonetz worldwide. High heterogeneity of vegetation cover and microrelief complicates prediction of Solonetz distribution using digital soil mapping (DSM). The aim of this study was to develop an approach for mapping Solonetz in forest-steppe landscapes of the Oka-Don Lowland using DSM techniques. The study was conducted at a key site (8.4 km²) in the southern Oka-Don Lowland. The dataset included 95 soil profiles, topography and vegetation covariates derived from Sentinel-1 and Sentinel-2. Soil description and classification followed the WRB system. Soil distribution was modeled using the Random Forest method at a spatial resolution of 10 m.

The resulting soil map shows that Calcic Gleyic Solonetz (Clayic, Aric) and Calcic Gleyic Solonetz (Clayic) occupy slightly concave, elongated depressions and cover about one quarter of the study area. Convex landforms are dominated by Dry Calcic Chernozem (Aric, Clayic) and Calcic Gleyic Chernozem (Aric, Clayic), accounting for nearly half of the area. Larger depressions are characterized by Planosols, Stagnosols, and Gleysols, while undisturbed Calcic Gleyic Chernozems occur mainly along depression margins.

The most important predictors were closed depressions and TPI layers derived from the DEM, and NDVI. These layers were contributed most to model performance. Vegetation types were predicted with optical and SAR data improved discrimination between woody vegetation, meadows, and agricultural fields.

The overall map accuracy reached 75%. Solonetz soils had the lowest accuracy due to complex spatial positions, occurring in shallow depressions within fields with xerophytic vegetation. Its classification improved Solonetz detection by 10–15%. Chernozems were predicted with highest accuracy, supported by more sampling points and association with agricultural fields. Soils in deeper depressions were mapped less precisely.

DSM delineated forest-steppe soils on undrained interfluves and in closed depressions (Solonetz). The accuracy of soil determination strongly depended on the integration of multisource remote sensing data, terrain and vegetation indices, enhancing detection of Solonetz in fields and deeper depressions.

# Comparative Study on Soil Spatial Provenance Based on Soil Property Similarity Clustering and Pedogenic Environment Inference

**Yun Shen[1*], Rong Zeng[1*]**

[1] *School of Geographic Science, Nanjing University of Information Science and Technology, Nanjing 210044, China*

*rzeng@nuist.edu.cn

**ABSTRACT**

Soil spatial traceability has significant application value in forensic soil science and judicial identification. This study, based on 265 surface soil samples from Anhui Province, compares two soil provenance strategies: (1) a similarity-matching and spatial clustering approach, which filters similar samples using spectral and physicochemical property similarities and applies the DBSCAN algorithm to determine the potential source area of unknown samples; (2) an inverse inference approach based on pedogenic environmental factors, which employs a random forest model to predict environmental variables such as soil parent material, land use, topography, climate, and vegetation, and infers provenance by integrating spatial distribution maps. By simulating provenance analysis, the accuracy and applicability of the two strategies are evaluated. The results indicate that the similarity-matching strategy achieves higher localization accuracy under conditions of strong spatial proximity and well-established databases, while the inverse pedogenic environment inference strategy demonstrates superior spatial constraint capabilities in regions with limited databases or strong spatial heterogeneity. Each strategy has its own advantages, and their integrated application holds promise for further improving the accuracy and resolution of soil spatial provenance analysis.

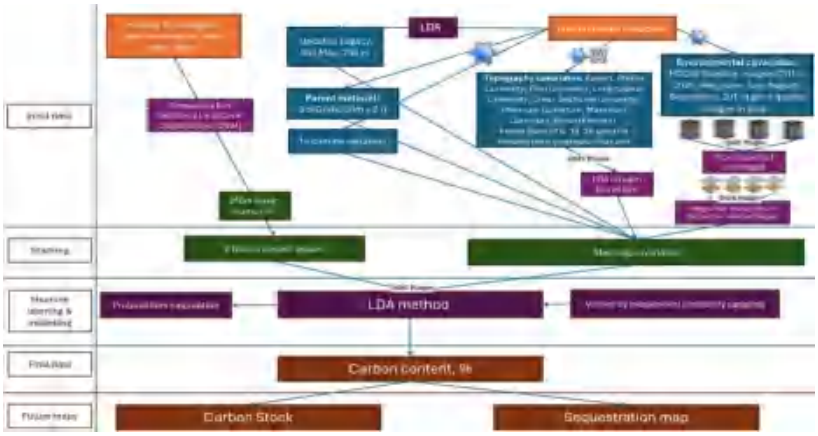
## ABSTRACT



Accurate spatial data on soil organic carbon (SOC) stocks as well as degradation and climate risks are indispensable for informing national climate strategies and the implementation of Nature-Based Solutions (NBS). This study demonstrates a scalable and cost-effective digital soil mapping (DSM) approach to update legacy soil information and model SOC stock and dynamics, with a specific focus on identifying carbon loss hotspots for policymakers. The methodological framework could be applied within the NBS digital platform for planning land restoration activities such as a platform developed by the Centre of Digital Technologies for NBS at HSE University.

DSM approach (Picture 1) tested on the arable lands of the Republic of Tatarstan (4.5 M ha), integrates the national 1:2.5M scale legacy soil map with a multi-source predictors system. This system employs Hierarchical Factor Analysis on multi-annual MODIS satellite imagery (2013–2025) to derive invariant soil and landscape states, representing integral gradients of productivity, thermal, and moisture regimes, alongside morphometric variables. While Linear Discriminant Analysis (LDA) was selected for modeling due to its interpretability, deriving a linear decision boundary defined by coefficients directly linked to predictor contributions, other algorithms, such as Random Forest and Neural Networks, were also tested showing comparable accuracy results. Model performance is quantified using a contingency matrix, from which overall accuracy and weighted and unweighted Cohen's kappa is derived. This assessment allows for the iterative refinement of the predictor set or the class structure if necessary. Trained on generalized soil classes from the legacy map and complemented with field-level SOC content data, the LDA model generated a refined, pixel-level predictive soil map with more than 60% overall accuracy tested on independent probability sample.

The resulting 250m resolution soil map and SOC stock map serve as environmental covariates. Within the NBS platform, they facilitate the enhancement of national-scale SOC stock models (e.g., Romanenkov et al., 2024). By integrating this updated pedological basis with dynamic data on land use and management practices, the platform can model SOC sequestration potential and, conversely, delineate areas at high risk of carbon loss, identified as hotspots. The presented DSM approach provides a reproducible and resource-efficient tool with probabilistic translations, offering policymakers a robust, data-driven foundation for targeting conservation efforts and monitoring the efficacy of land management policies across regions.

# Spatially-Explicit Uncertainty and Feature Attribution in Landscape-Scale Topsoil Carbon Mapping in Forest-Steppe

**Danila R. Bardashov[1], Pavel P. Fil[1], Pavel P. Krechetov[2]**

[1] *V. V. Dokuchaev Soil Science Institute*

[2]*Lomonosov Moscow State University*

*alperf97@gmail.com

**ABSTRACT**

Forest-steppe landscapes exhibit pronounced soil organic carbon (SOC) variability formed by biotope mosaics, yet spatial uncertainty patterns remain poorly characterized. This study combines topsoil (0-15 cm) SOC mapping with spatially-explicit uncertainty and feature attribution analysis in the Oka-Don Lowland forest-steppe (Tambov Region, Russia). We collected 413 samples using representative sampling and verified predictions at 42 locations across meadow-cropland, meadow-forest, and cropland-forest transitions.

Predictors included UAV-LiDAR micro-topography (2 m), multi-year Sentinel-2 phenology, vegetation/moisture indices, and ground-sampled pH. We compared hybrid CNN-LSTM-MLP model that processes spatial patches, temporal sequences, and tabular features against CatBoost, Cubist/SVR, and PLSR using spatially clustered cross-validation. Uncertainty was quantified via 1000-iteration bootstrap with prediction interval range (PIR) mapping.

CNN-LSTM-MLP achieved highest accuracy ($R^2$ = 0.67, RMSE = 5.8 g $kg^{-1}$) with narrowest PIR (23 g $kg^{-1}$), outperforming CatBoost ($R^2$ = 0.61) and PLSR ($R^2$ = 0.42). Spatial uncertainty mapping revealed 40-50% higher PIR in ecotones versus biotope interiors, with meadow-forest transitions showing maximum uncertainty (PIR = 35 g $kg^{-1}$).

Spatially-explicit SHAP (SHapley Additive exPlanations) analysis [1] revealed difference in feature importances between biotopes and ecotones. Forest interiors showed TWI dominance mean SHAP = 0.42, while in ecotones phenological variables had higher importance (EVI2 greenup, mean SHAP = 0.38 in forest-meadow transitions). Spatial SHAP variance mapping identified ecotones as feature importance instability zones.

Cross-model SHAP comparison showed deep learning architectures had 28% lower spatial variance than tree-based methods in homogeneous areas.

Our uncertainty-interpretability framework demonstrates ecotones as uncertainty hotspots requiring targeted sampling for precision carbon accounting. Bootstrap PIR identifies where uncertainty is high; SHAP reveals why through feature attribution instability.

# Integrating Digital Soil Mapping and Remote Sensing–Based Soil Moisture for Crop Water Requirement Modelling at the Land Parcel System Scale

**R. Napoli[1*], F. Faridani[1], C. Piccini[1], S.A. Pellegrini[2], N. Vignozzi[2] and B. Parisse[1]**

*rosario.napoli@crea.gov.it

**ABSTRACT**

This study aims to test an integrated methodology based on digital soil mapping techniques to generate spatially distributed data on soil physical and hydrological properties, supporting the assessment of crop irrigation requirements at a detailed spatial scale, such as irrigated parcels within the Land Parcel System. The approach complies with the requirements of the FAO dual crop model (Pereira et al., 2020) and is applied to selected areas in Central and Southern Italy managed by land reclamation consortia.

The data preparation process consists of several steps, moving from coarser to finer spatial scales through downscaling operations. Starting from the national CREA database of soil profiles, first a normalization of the measured basic physical and chemical properties (texture, organic carbon, pH, and bulk density) was carried out using a spline methodology (Bishop et al., 1999) at the FAO References depths: the surface layer (10 cm) and two root-zone depths (70 and 100 cm). The pedological data were then spatialized using a machine learning algorithm (Random Forest) at a 100 m resolution on an INSPIRE sub-grid as a first spatialization step. A set of 16 covariates transformed into raster format, including categorical variables, morphometric variables (DEM and derivatives), and variables derived from remote sensing imagery (Landsat OLI), were used after an appropriate resampling to the working spatial resolution.

Subsequently, the Pedotransfer functions (PTFs) with higher performance tested at the European level and implemented in R (Euptfv2; Szabó et al., 2021) were applied to the dataset to estimate hydrological properties, including: water content at field capacity, wilting point, saturated hydraulic conductivity (Ks, cm/day), and porosity (calculated from bulk density) at the three References depths. In a second step, downscaling to a 10 m resolution was performed in areas classified as irrigated in the Land Parcel System, evaluating and applying the most suitable resampling method (bicubic). To estimate soil moisture dynamics at the three depths, the Soil Moisture Analytical Relationship (SMAR) model (Manfreda et al., 2014) was applied using Sentinel-1 and Sentinel-2 imagery integrated through cloud computing approaches (Faridani et al., 2017). This method was considered the only feasible approach at such a high spatial resolution and pixel density, compared to point-based physically based hydrological models. The results allowed us to track and estimate uncertainties at the various stages, including the spatialization, the application of PTFs, and the SMAR model, using point-based measured datasets—both physical and hydrological—from the national CREA database. Overall, the study demonstrates the feasibility of integrating multiple methodologies and data sources to support assessments at an extremely detailed spatial scale.

# Model Selection for Digital Soil Mapping Using Spatial Structure Indices

**Fang-He Zhao**[1*]

[1] *State Key Laboratory of Resources and Environmental Information System, Institute of Geographic Sciences and Natural Resources Research, Chinese Academy of Sciences, Beijing 100101, China*

*zhaofh@lreis.ac.cn

**ABSTRACT**

The selection of models for digital soil mapping relies on different assumptions regarding the spatial structure of soil properties. Accurately recognizing this structure is therefore critical for selecting appropriate models. However, the potential of spatial structure characterization for guiding model selection in digital soil mapping remains underexplored. This limitation largely stems from the difficulty of quantifying spatial structure when soil observations are sparse and full spatial coverage of the target soil property is unavailable.

In this study, we employ recently developed spatial structure indices derived from limited soil samples and environmental covariates to support model selection in digital soil mapping. A case base comprising 80 soil property prediction scenarios with consistent prediction targets and comparable analytical scales is constructed for evaluation. Two representative model types are analyzed: Ordinary Kriging (OK), representing spatial-autocorrelation-based geostatistical models, and Random Forest (RF), representing covariate-based machine learning models.

The results demonstrate that spatial structural characteristics of the soil–environment system are closely linked to model performance. Based on these characteristics, appropriate model types can be identified with an overall accuracy of 82.9%. These findings indicate that spatial structure indices provide an effective and explainable basis for model selection in digital soil mapping, bridging spatial structure analysis and predictive modeling under sample-limited conditions.

# Enhancing Regional Topsoil Total Nitrogen Mapping through Differentiated Fusion of Ground Hyperspectral Data and Satellite Images Under Low Vegetation Cover

Meng Jihua, mengjh@aircas.ac.cn, 13911012239 (China, CHN, +86), 13636140136 (China, CHN, +86)

**ABSTRACT**

Total nitrogen in soil (STN) serves as a crucial indicator of soil nutrient content and provides an essential nitrogen source necessary for crop growth. Precise inversion of STN content is essential for the sustainable use of soil resources and the advancement of agricultural development, particularly to achieve efficient fertilization. However, due to the weak spectral signals of STN and the interference of mixed cropping farmland vegetation cover, achieving high-resolution measurement and precise characterization of STN heterogeneity using satellite remote sensing remains a challenge. In this study, conducted in Zouping City, Shandong Province, we propose a method based on the Differentiated Fusion of Enhanced Multispectral Image Bands (DFE_MSIBs) combined with machine learning algorithms for the spectral inversion of STN content. First, a vegetation-soil spectral unmixing model was applied to reduce the influence of photosynthetic vegetation spectra on soil property spectra under low vegetation cover. Second, we integrated Sentinel-2A multispectral images with ground-based hyperspectral data using Non-negative Matrix Factorization (NMF) to construct the DFE_MSIBs . Finally, we compared the performance of Partial Least Squares Regression (PLSR), Random Forest (RF), and Convolutional Neural Networks (CNN) for STN inversion, incorporating a comprehensive set of predictors including vegetation indices, soil indices, environmental variables, topographic factors, and Sentinel-1 SAR data.The findings demonstrate that the enhanced spectral characteristics and differentiated fusion method not only strengthen the relationship between STN and Sentinel-2A MSI data but also enhance the precision of regional STN inversion models. The DFE_MSIBs method combined with the Random Forest (RF) algorithm yielded the optimal performance, with a Coefficient of Determination $R^2$ of 0.95, Root Mean Square Error (RMSE) of 0.10 g/kg, and Lin's Concordance Correlation Coefficient (LCCC) of 0.89. Compared to the unfused model, the average $R^2$ value increased by 0.02, and the average RMSE decreased by 0.01 g/kg. Additionally, Sentinel-1 SAR data (VV and VH polarization) proved to be the most critical predictor variables across all models. These findings hold practical significance for utilizing multi-source remote sensing data in STN mapping and precision fertilization in agricultural fields15.

**ABSTRACT**

MapBiomas Soil is a collaborative initiative that produces annual soil information for Brazil through successive collections that incorporate new data and methodological innovations. Collection 3 introduces a compositional modelling strategy to represent soil particle-size fractions and coarse fragments consistently across the soil profile at the national scale.

Harmonized field soil observations from the SoilData repository (60,883 particle-size observations) were integrated with environmental covariates within a digital soil mapping framework implemented in Google Earth Engine at 30 m spatial resolution. Sand, silt, clay (fine earth), and coarse fragments (all particles larger than sand) were modelled jointly as components of the whole soil using additive log-ratio (alr) transformations, with clay as the References component. Modelling was performed on a mass basis, with fine-earth fractions rescaled to sum to 100% (sand + silt + clay) before compositional transformation. Gradient Boosted Model Trees (GBM) were fitted separately for successive 10 cm depth intervals from the surface to 100 cm.

Predicted fractions were back-transformed to the original compositional space to reconstruct particle-size distributions at each depth. Coarse-fragment mass fractions were converted to volumetric proportions using density estimates for fine earth and lithological materials. Depth intervals in which coarse fragments accounted for 100% of the soil volume were interpreted as the effective termination of the soil profile. Functional soil depth metrics were derived using two thresholds: dominant stoniness (50% coarse-fragment volume) and extreme stoniness (90%).

Results show that, while medium-textured soils dominate the surface layer (0–30 cm) across Brazil, clayey textures become predominant between 60 and 100 cm depth at the national scale. Sandy and coarse-textured soils are more frequent in savanna and semi-arid regions, whereas fine-textured soils dominate humid forested regions. Maps of coarse-fragment volume indicate that most of the Brazilian territory is characterized by low stoniness, but localized shallow and highly stony soils impose strong vertical constraints on soil depth and land-use suitability.

This modelling framework enables the consistent derivation of particle-size fractions, texture classes, and functional soil depth at large spatial extents and represents the main methodological innovation of MapBiomas Soil Collection 3, with potential applicability to other national-scale soil information systems.

**ABSTRACT**

Digital soil mapping (DSM) in extensive territories often relies on sparse geoReferencesd profiles, despite the existence of massive volumes of soil analyses in commercial laboratory databases. The utility of this commercial data is frequently limited by privacy restrictions and lack of coordinates, generally aggregated to the municipality level. This study proposes an alternative for utilizing such data by investigating a “distributional consistency check" as a complementary validation strategy for national-scale soil maps. We propose a methodological framework to assess whether 30m-resolution DSM predictions can be reliably evaluated against aggregated, non-geoReferencesd datasets. The investigation focuses on developing quantitative diagnostics that can function despite the uncertainty of sample support (unknown mix of point samples and field composites). We evaluate statistical resampling techniques to generate synthetic sample vectors from aggregated, binned frequency data from commercial laboratories, aiming to estimate population parameters while accounting for quantization uncertainty. We assess whether distributional comparisons (e.g., dispersion and shape alignment) remain valid when the physical support of the References data is unknown. We investigate theoretical bounds to distinguish between legitimate scaling effects (field averaging) and potential map errors (smoothing artifacts). We then test the sensitivity of histogram dissimilarity metrics to identify those most suitable for detecting systematic biases between the predicted map and the commercial "ground truth," regardless of the underlying sampling scheme. Among these, we introduce the Wasserstein metric (Earth Mover's Distance)—a measure that honors the topology of the histogram space and has been underexplored in pedometrics—as a useful diagnostic tool. This work aims to determine the operational viability of using non-spatial commercial data to quality-check digital soil maps. By rigorously testing these distributional diagnostics, we seek to establish a protocol that allows for the utilization of available commercial data to ensure map consistency with regional agronomic statistics.

# Modelling and mapping land susceptibility to degradation and desertification in Europe

**Remus PRĂVĂLIE** [1, 2] *

[1] *University of Bucharest, Faculty of Geography, 1 Nicolae Bălcescu Street, 010041, Bucharest, Romania,*

* pravalie_remus@yahoo.com

**ABSTRACT**

Land degradation and desertification emerge as increasingly serious environmental challenges, impacting extensive regions worldwide, including large areas of Europe. Achieving a comprehensive understanding of these complex degradation processes requires the application of multicriteria integrated approaches, such as the MEDALUS (*Mediterranean Desertification and Land Use*) framework, which has been widely applied in scientific studies to identify land areas sensitive to degradation and desertification across multiple spatial scales. This scientific work investigates land susceptibility to degradation and desertification at a continental scale by integrating, modelling and mapping various environmental factors responsible for land degradative conditions, which were derived from multiple geospatial datasets covering 40 European countries. More specifically, using a significantly improved MEDALUS framework, a total of 24 environmental variables and 7 environmental quality indices were integrated and processed as direct and indirect driving forces of environmental degradation. The refinement of the MEDALUS framework is justified by its methodological flexibility and the geographical diversity of Europe (with multiple environmental conditions influencing land degradation and desertification), and involved the integration of 11 new environmental parameters (in addition to 13 variables of the original MEDALUS scheme) and 3 supplementary quality indices (in addition to 4 standard indices) into a final geospatial product, called Land Degradation and Desertification Sensitivity Index. The cartographic results revealed a complex and heterogeneous spatial pattern of land susceptibility to degradation and desertification across Europe, with many hotspots of environmental degradation throughout the continent and with significant epicenters of desertification, particularly in the Mediterranean region. The geospatial (and statistical) findings provide a comprehensive assessment of pan-European lands exposed to varying levels of degradation and desertification, delivering useful insights for the European Union's and governmental policies addressing these environmental threats across the continent.

# Soil Organic Carbon Spectral Modeling with MIR in Carbonate-Rich Soils Requires Temperature Ramping References Data for Reliable Training.

**Gbenga D. Adejumo* and Derek Peak**

*Department of Soil Science, University of Saskatchewan, Saskatoon, SK S7N 5A8, Canada.*

gbenga.adejumo@usask.ca

**ABSTRACT**

We evaluated whether errors in predicting soil organic carbon (SOC) via Near Infrared (NIR) with models developed via acid digestion References values can be eliminated by using Mid Infrared (MIR) spectra. NIR and MIR spectral data were acquired on soil samples ($n$ = 403) collected from carbonate-rich Saskatchewan agricultural soils, and values for organic and inorganic carbon were measured with both acid digestion and temperature ramping methods. Soil spectra were processed with continuous wavelet transform then analyzed with cubist regression models using a 70:30 train-test split approach. Spectral feature selection, wavelet scales, models and hyperparameters were optimized on the training dataset using 5-fold cross-validation, while model validation was performed on the testing dataset. Temperature ramping data led to separation of spectral features selected for SOC and SIC model training, whereas acid digestion References data showed overlapping features at 9940, 8156, 7231, and 4199 $cm^{-1}$. The temperature ramping method resulted in higher model accuracy for SOC and SIC compared to the acid digestion method for both NIR and MIR. Applying spectral features selected from temperature ramping data to train models on acid digestion References values did not affect SOC and SIC model accuracy. This study concluded that model performance differences are driven more by the quality and consistency of the References data rather than the choice of spectroscopic wavelength or spectral feature selections.

**ABSTRACT**

Traditional soil testing is slow and costly. Visble-near infrared (Vis-NIR) spectroscopy offers a faster alternative for precision agriculture and soil health assessment. A compact Micro NIR sensor (NIRONE, 2000–2450 nm) was compared to a mobile Vis-NIR system (305-1700 nm) to predict pH, total organic carbon (TOC), phosphorus (P), potassium (K), magnesium ($Mg^{2+}$), and calcium ($Ca^{2+}$). spectra of prepared soils (n=145) were modeled with Partial Least Squares Regression (PLSR), Support Vector Machines (SVM), and Random Forest (RF) under 5-fold cross-validation and an independent test set. Many preprocessing pipelines (smoothing, derivatives, SNV, MSC, detrending, baseline correction) were optimized and used to enhance the predictive accuracy of the models. The micro-NIR often matched the Vis–NIR for several targets: pH (micro-NIR R = 0.84, RMSE = 0.24; Vis-NIR R = 0.74, RMSE = 0.27), TOC (0.83, 1.62 %; 0.86, 1.12 %), K (0.74, 6.42 mg/100 g; 0.77, 6.15 mg/100 g), and $Ca^{2+}$ (0.87, 463.9; 0.88, 457.7 mg/100 g). The Vis-NIR was stronger for $Mg^{2+}$ (0.79, 5.9 mg/100 g vs 0.59, 9.29 mg/100 g). Both instruments showed only modest predictive accuracy for P (Vis–NIR 0.56, 7.01 mg/100 g; micro-NIR 0.5, 9.11 mg/100 g). Across properties, preprocessing optimization and algorithm choice were the main drivers of accuracy; no single pipeline dominated. The micro-NIR sensor shows strong potential for soil property prediction and is suitable for routine laboratory and field measurements due to its compact size, low cost, and competitive predictive accuracy.

# Intelligent Soil Monitoring

**Yongsheng Hong**[1*]

[1] *School of Resource and Environmental Sciences, Wuhan University, Wuhan, China*

*hys@whu.edu.cn

**ABSTRACT**

The advancement of soil remote sensing toward intelligent monitoring and information-based management requires the integration of spectral theory, multi-source data fusion, and artificial intelligence. This presentation summarizes a five-part research framework that progressively builds from physical spectral mechanisms to large-scale, intelligent soil information systems.

Section One: Fractional-order Derivative (FOD)

Fractional-order derivative introduces a continuous mathematical formulation to enhance soil spectral information processing. By adjusting derivative order within a non-integer domain, FOD effectively amplifies subtle spectral features while maintaining signal integrity. This method advances traditional preprocessing techniques by balancing spectral resolution and stability, providing a new theoretical foundation for intelligent spectral analysis across soil and environmental sensing applications.

Section Two: Multi-sensor Spectral Fusion

The integration of visible–near infrared (VIS–NIR) and mid-infrared (MIR) spectral data represents a key step toward multi-source information synergy. Through algorithms such as continuous wavelet transform and optimal band combination, complementary features from multiple spectral domains are jointly utilized to enhance prediction accuracy and efficiency. This multi-sensor fusion demonstrates the potential of cross-domain spectral integration for soil property monitoring and data-driven environmental assessment.

Section Three: Large Soil Spectral Library

Global and regional soil spectral libraries serve as essential data infrastructures for intelligent soil monitoring. Leveraging big-data analytics, fractional-order transformations, and deep learning models such as convolutional neural networks (CNN), large-scale libraries enable robust and transferable models despite data heterogeneity. These databases function as both knowledge repositories and algorithm training grounds, laying the foundation for universal soil spectral intelligence systems.

Section Four: Airborne Hyperspectral Observation

Airborne hyperspectral imaging provides fine spatial and spectral detail for soil mapping at field to landscape scales. As an intermediate observation level between laboratory and satellite sensing, airborne platforms enable the validation and refinement of predictive models under real-world environmental conditions. Their integration into soil monitoring workflows enhances both spatial continuity and spectral interpretability, supporting precision agriculture and environmental diagnostics.

Section Five: Bridging Laboratory Spectra and Satellite Imagery

To achieve large-area and cost-effective soil monitoring, an integrative framework was developed to link laboratory VNIR–SWIR spectra with multispectral satellite data. By simulating hyperspectral features from Landsat-8 imagery and applying fractional-order preprocessing, this approach reduces the scale and spectral gaps between in-situ measurements and satellite observations. The resulting system enables consistent, scalable, and intelligent SOC prediction and mapping under natural conditions.

Collectively, these five research directions outline a comprehensive pathway toward intelligent soil remote sensing, characterized by adaptive spectral modeling, data-driven fusion, and multi-platform integration. This framework not only enhances the monitoring of soil carbon but also establishes a methodological foundation for digital, automated, and knowledge-based soil information systems in support of sustainable land and ecosystem management.

# Evaluating Portable X-Ray Fluorescence (pXRF) for Soil Fertility Assessment: Influence of Moisture and Soil Properties

## ABSTRACT

Rapid and scalable soil health assessment is essential for precision agriculture, yet routine wet-chemistry analyses remain slow, and costly for large-area monitoring. Portable X-ray fluorescence (pXRF) spectroscopy offers a promising proximal-sensing solution for rapid multi-element detection, but its performance is often constrained by soil moisture, matrix effects, and the weak relationship between total and plant-available nutrient pools. This study evaluated 113 soils collected from 0-120 cm depth across eastern Washington to (i) quantify how soil moisture influences pXRF elemental detectability, (ii) develop prediction models for soil pH and available nutrients, and (iii) assess the potential of pXRF-based predictions for regional soil health mapping. Soils were analyzed under four moisture states: dry (DS), field-moist (FM), saturated paste (SP), and after removal of excess water (AREW) to reflect realistic field and laboratory scenarios. Moisture substantially affected pXRF signals, with mobile elements showing greater attenuation than immobile mineral-bound elements. Despite this, pXRF exhibited strong predictive capacity for macronutrients such as K, Ca, and Mg ($R^2$ up to 0.8 in DS and SP). Prediction accuracy improved markedly when soil pH and organic matter (OM) were incorporated into regression models, increasing $R^2$ values by 1.1 - 6.1-fold compared to pXRF-only models. Micronutrient predictions (Cu, Zn) were weaker, driven by low concentrations and greater geochemical variability. Among moisture conditions, SP consistently produced the most stable models, likely due to improved particle homogeneity and surface smoothness that reduce density-related X-ray scattering. Cross-validation confirmed strong generalization for macronutrients but lower stability for Cu and Zn. Spatial mapping using pXRF derived predictions reproduced regional gradients of acidity and nutrient status, demonstrating strong utility for reconnaissance level soil health surveillance. However, agronomic category comparisons revealed variable agreement with laboratory data: Ca and Mg classifications were highly stable (<3% mismatch), whereas pH, P, and Cu showed higher misclassification near critical management thresholds. Thus, pXRF based predictions can guide regional monitoring and sampling prioritization, however laboratory confirmation remains necessary for fertilizer recommendations. Overall, combining pXRF with key soil properties under controlled moisture conditions enhances the speed, resolution, and practicality of soil fertility monitoring. This work demonstrates the growing potential of proximal sensing technologies to serve as foundational tools in future soil fertility assessment systems.

# Low-cost portable near infrared spectroscopy for in-situ and laboratory prediction of soil organic carbon in Ferrosols

**ABSTRACT**

Soil organic carbon (SOC) is critical to maintaining soil health and ecosystem functioning. Reliable quantification of SOC is therefore essential for evaluating soil fertility and guiding carbon management strategies. near-infrared spectroscopy (NIRS) provides a rapid, non-destructive, and cost-efficient approach for SOC estimation; however, conventional commonly used spectrometers remain prohibitively expensive for widespread use. This study evaluated the potential of the low-cost portable NeoSpectra spectrometer for SOC prediction using soils from typical Ferralsols collected in Jiangxi Province, China. The spectral data were converted to absorbance and processed using the Savitzky–Golay first-derivative smoothing before model calibration. Predictive models included Cubist, random forest (RF), partial least squares regression (PLSR), memory-based learning (MBL), a simple ensemble model, and a spectral-guided ensemble approach. For in-situ condition, the ensemble and spectral-guided ensemble models performed best, with coefficient of determination (R2) of 0.72 and 0.70, and root mean square error (RMSE) of 5.95 g kg-1 and 6.16 g kg-1, respectively. The RF model showed slightly lower yet acceptable performance (R2 = 0.62, RMSE = 6.90 g kg-1). For laboratory condition, the two ensemble strategies again outperformed the other models (R2 = 0.85 and 0.85; RMSE = 4.15 and 4.07 g kg-1), while the RF model remained acceptable ($R^2$ = 0.77, RMSE = 5.10 g kg-1). These findings demonstrate that the NeoSpectra spectrometer, when combined with appropriate preprocessing and ensemble modeling, can provide reliable SOC estimates, representing a viable and lower-cost alternative for routine soil monitoring and regional carbon assessments.

**ABSTRACT**

Modern agricultural monitoring demand precise and timely information of soil properties. In recent years, soil spectroscopy has become widespread method as an effective alternative to traditional laboratory analysis of soil samples [1]. However, existing approaches encounter a range of methodological constraints, among which is a dependence of model accuracy on the sampling size. Spectral prediction of soil properties mainly is based on large datasets (n > 100), which often is not easy to collect. Practical survey are often restricted to 20-50 samples per field, primarily due to economic and time constrains. When soil properties are highly correlated with each other, predicting each property individually directly from the spectra can be optimized. This can be done by indirect prediction [2].

The objective of our study was to develop a sequential indirect modeling (SIM) method for predicting soil properties from spectral reflectance data with small sample datasets (n = 30). We focus on analysis of the relationship between soil properties (SOC, available P, total N, pH, and main exchangeable cations) and soil samples spectra, and perform SIM method among the most highly correlated properties. It allows for the indirect prediction of parameters that are difficult to model directly (for example, pH or available P) through those that are more easily predicted (for example, SOC content). The physicochemical validity of these relationships (for example, the correlation between SOC content and total N) provides additional reliability of predictions.

SIM approach for several soil properties was successfully tested on a number of plots. The most effective method proved to be regression techniques such as PLSR, PCR, RF, SVR. These methods enable efficient use of the available data, minimize the negative effects associated with small sampling sizes, reduce the risk of overfitting, and provide reliable predictions. The outcomes of this analysis were employed to enhance the accuracy of agrochemical soil mapping under constrained resources for sampling and analysis.

## ABSTRACT

Appropriate nutrient management is essential for improving nutrient use efficiency and preventing environmental pollution caused by excessive fertilizer application. Therefore, continuous monitoring of soil nutrient levels during crop growth is required. However, there are no available sensors for real-time measurement of soil nutrient contents. Since electrical conductivity (EC) reflects ionic concentrations in soil solutions, this study evaluated the applicability of EC sensors for real-time prediction of available nutrient levels in soil. The objective of this study was to assess EC sensor responses to nitrogen and potassium fertilization and to evaluate its applicability under field conditions. In the laboratory, nitrogen and potassium were sequentially applied to achieve cumulative application rates of 0.25, 0.5, 0.75, 1, 1.25, 1.5, 2, and 3 times of the standard fertilization amount. The observed EC variations were analyzed to quantify the relationship between cumulative fertilizer input and sensor response. The increase in sensor-based EC responded linearly to fertilizer input between 0.25 and 1.25 times the standard fertilization rate, but at higher application levels, the relationship was better explained by a nonlinear saturation model. The sensor-based EC values showed a strong correlation with soil ammonium nitrogen ($NH_4^+$-N) released by urea hydrolysis, indicating that EC sensors effectively reflected the applied fertilizer in soil. In the open-field pepper soil, the increases in sensor-based EC following nitrogen and potassium fertigation were well predicted by the linear and nonlinear saturation models established through laboratory-based fertilizer monitoring. This indicated that the relationships established under laboratory conditions were also applicable under field conditions. Real-time monitoring of soil nutrients using EC sensors would be beneficial for nutrient management in open-field cultivation.

# Coastal Soil Salinity Inversion Using Resource Satellite Data and Explainable Machine Learning: A Case Study of Southern Laizhou Bay

**Rui Ma[1], Jianrong Cao[1]**

[1] School of Geography and Environment, Liaocheng University, Liaocheng252000, China

13155422565@163.com

**ABSTRACT**

Soil salinization in coastal regions is a significant manifestation of global coastal land degradation, posing significant threats to agricultural sustainability and the stability of ecosystems.. In China, coastal areas are particularly affected by extensive salinization, making this issue increasingly urgent. Recent factors such as sea-level rise, seawater intrusion, and improper irrigation practices have further exacerbated coastal soil salinity. This study aims to quantitatively estimate soil salinity levels in the southern Laizhou Bay area using interpretable machine learning and feature selection strategies, with the goal of determining the extent and proportion of soil salinization.. The southern shore of Laizhou Bay in Shandong Province was selected as the study area. The research utilized four raw bands (blue, green, red, and near-infrared) from ZY1-02D VNIC, along with derived data: 9 vegetation indices, 13 salinity indices, three principal component datasets, and eight texture feature datasets. These were integrated with 66 measured soil salinity data points (ranging from 0.4 to 33 g/kg) to develop an inversion model for soil salinization. Correlations between 37 feature variables and soil salinity were first analyzed, with significant correlations at the 0.01 level retained for further examination.. Four feature selection methods: Grey Relational Analysis (GRA), Variable Importance in Projection (VIP), Gradient Boosting Machine (GBM), and Recursive Feature Elimination (RFE) were applied. Five machine learning models: Backpropagation Neural Networks (BPNN), Random Forest (RF), Classificatory Boosting Trees (CatBoost), Adaptive Boosting (AdaBoost), and Extreme Gradient Boosting (XGBoost) were tested. The optimal model was selected using grid search combined with five-fold cross-validation. The SHAP method was used to analyze the influence of input variables on model performance, resulting in an inversion map for the study area. The findings indicate that the GBM-BPNN model achieved the best performance for soil salinity inversion ($R^2$ = 0.72, RMSE = 4.24 g/kg, RPD = 1.94). Among the five feature categories, vegetation indices were found to play the most significant role, with four of the seven GBM-selected variables being vegetation indices ("GDVI", "GRVI", "GARI", "EVI"). SHAP analysis revealed that GRVI were the most influential. The results show that moderate and mild salinization dominate the Laizhou Bay area, comprising 56.4% of the total area. Salinity increases from south to north, consistent with results from back-distance weighted interpolation of measured samples. This study demonstrates that the proposed methodology offers superior accuracy compared to traditional geostatistical approaches and highlights the importance of feature selection when sample sizes are limited. Additionally, the study elucidates how features influence model performance, providing a scientific basis for coastal ecological management.

**ABSTRACT**

Rapid and accurate organic matter (SOM) determination is essential for sustainable agricultural management, but conventional laboratory analyses are expensive and time-intensive. Although smartphone-based soil imaging presents a viable alternative, existing methods suffer from limited accuracy and poor cross-condition generalization. We present a novel deep metric learning framework that transforms SOM prediction from a regression problem into a similarity-based learning task using smartphone-captured soil images. Our approach employs a Triplet Loss neural network architecture to map soil images into an embedding space where geometric distances reflect SOM content differences. The framework integrates automated image quality evaluation through the Blind/Referencesless Image Spatial Quality Evaluator (BRISQUE) combined with super-resolution enhancement to optimize input data quality. Testing with 500 soil samples from Southern Ontario revealed that our similarity-based framework (validation RMSE = 0.17) substantially outperformed conventional regression approaches (validation RMSE = 0.51 for Random Forest). The model exhibited robust performance across varying soil textures (RMSE variation <0.05 among texture classes) and diverse environmental conditions (temperature 20-30°C, humidity 45-75% RH). With a processing time of only 2.3 seconds per sample, the framework is well-suited for real-time field deployment. This similarity-based paradigm overcomes key limitations in digital soil sensing by enabling fast, accurate, and user-friendly SOM quantification, thereby advancing precision agriculture soil monitoring capabilities. Our results highlight the transformative potential of metric learning approaches for digital soil analysis and their contribution to sustainable farming practices.

**ABSTRACT**

Soil heavy metal contamination can lead to long-term environmental risks in mining areas. Hyperspectral remote sensing combined with machine learning models is a promising approach for monitoring soil heavy metal concentrations. However, the high dimensionality of soil spectra makes it difficult to directly use spectral data for accurate prediction, often leading to model overfitting. Therefore, key challenges for extracting spectral features and improving the accuracy and transferability of predictive models remain. This study aims to overcome these limitations by proposing an end-to-end hyperspectral remote sensing workflow to enhance model cross-regional applicability. In this study, 647 surface soil samples (0-20 cm) were collected from an abandoned tailing area in western Inner Mongolia. Soil spectral reflectance was measured using a PSR+ spectrometer, and soil heavy metal concentrations were determined using ICP-MS. To improve data quality, 11 preprocessing methods were applied, forming 180 combinations through baseline correction, scatter correction, smoothing, and scaling. These combinations were evaluated for their correlation and predictive performance, with the best combinations selected. Furthermore, 16 wavelength selection methods were tested, which were classified into filter, wrapper, and embedded approaches, focusing on Competitive Adaptive Reweighted Sampling (CARS), Variable Iterative Space Shrinkage (VISSA), and Successive Projections Algorithm (SPA). During the feature construction phase, Optimized Spectral Indices (Opt-TBIs) and Continuous Wavelet Transform (CWT) were used to improve the expression for inter-band information. Finally, the optimal wavelengths were combined with Decision Tree (DT), Random Forest (RF), and Gradient Boosting Decision Tree (GBDT) models to predict soil heavy metal concentrations. The results showed that the best-performing bands were obtained through pairwise combinations of preprocessing, with First Derivative (1FD) and Multivariate Scatter Correction (MSC) that was the most robust performance across all heavy metals. Regarding wavelength selection, the wrapper method exhibited the best prediction performance, with effective wavelengths concentrated in the 496–750 nm and 1829–2400 nm ranges. CARS and VISSA were more effective in capturing copper and chromium features, while SPA in predicting zinc and lead showed the best performance. Using Opt-TBIs to enhance inter-band correlation, combined with the GBDT model, demonstrates excellent predictive accuracy and stability, with an independent validation $R^2$ of approximately 0.87. In conclusion, the end-to-end hyperspectral remote sensing workflow enhances the accuracy and transferability of predictions for soil heavy metal concentrations, providing an innovative solution for monitoring soil contamination in mining areas.

# Multi-Element Synergy-Driven Transfer Learning Model for Enhancing the Generality of Soil Heavy Metal Concentration Estimating

**Chang Meng[1*] Fei Li[1] Mei Hong[2]**

[1] *Inner Mongolia Agricultural University, College of Resources and Environment, Hohhot, China;*

[2]*Inner Mongolia Minzu University, College of Grassland Science, Tongliao, China.*

* 2021202040012@emails.imau.edu.cn

**ABSTRACT**

Soil heavy metal contamination poses a long-term threat to agricultural sustainability and ecological security. Remote sensing technology offers a non-invasive, large-scale method for monitoring soil heavy metal concentrations, providing an effective alternative to traditional soil analysis. However, monitoring models are often influenced by variations in soil active components (such as organic matter and iron) across regions, which can reduces model accuracy and generalization ability. To address this, this study proposed a multi-element synergistic transfer learning model (Tr-MORF), which leverages the inherent absorption characteristics and antagonistic effects between metals and soil active components to solve domain adaptation problems in cross-regional predictions. In this study, 488 surface soil samples (0-20 cm) were collected from two tailing areas in western and northern Inner Mongolia. Soil spectral reflectance was measured using a PSR+ spectrometer, and heavy metal concentrations and active soil components were analyzed through laboratory wet chemical methods. To enhance spectral reflectance, a Fractional Order Derivative (FOD) method was used to highlight subtle spectral features. The MORF model was then employed to jointly predict concentrations of Zn, Cr, As, Cd, Pb, and Cu. To further improve cross-regional prediction accuracy, several transfer strategies (Recalibrated, Parameter-based, TCA, KMM, and TrAdaBoostR2) were integrated into a multi-output framework to assess their adaptability in estimating soil heavy metal concentrations. The results showed that the 1.2-order FOD method significantly improved the capture of subtle spectral features and enhanced spectral expression. The key soil heavy metal bands selected by the FOD-enhanced MORF model were found in regions associated with active soil components, indicating a synergistic effect between metals and active components. Joint modeling effectively integrated this information reduced negative impacts and enhanced the model's generalization ability. The combination of transfer learning and the MORF model significantly improved cross-regional transferability, with nRMSE decreasing by 6.35% to 11.24% and $R^2$, which was increased by 7.05% to 16.04%. Cu, Pb, and Zn exhibited the highest transferability, followed by Cd and As. Notably, the Tr-MORF model demonstrated high prediction accuracy and consistency when validated with publicly available soil data, demonstrating its applicability across different regions and scales. In conclusion, the Tr-MORF transfer learning model significantly improves adaptability and transferability across regions, providing an innovative solution for precise soil pollution monitoring.

# A transferable spatiotemporal deep learning framework integrating soil moisture dynamics for high-resolution cropland Soil Organic Matter Mapping Across Regions

**Chong Luo[1*], Jiale Geng[1], and Huanjun Liu[1]**

*1 Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun, 130102, China*

**ABSTRACT**

Soil organic matter (SOM) is a critical indicator of soil health and agricultural sustainability, yet achieving high-resolution mapping at large scales remains challenging due to the complex interplay of environmental drivers, particularly soil moisture dynamics. This study introduces a novel spatiotemporal deep learning framework, ExP-C, that incorporates reconstructed soil moisture dynamic feedback sequences (SMDFS) to enhance SOM prediction accuracy. Focusing on two major black soil regions—Northeast China (1.24 million km²) and the U.S. Mississippi River Basin (1.35 million km²)—we compiled 2,616 topsoil (0-20 cm) samples from field surveys (2014-2024) and the WoSIS database, integrated with Landsat-8 OLI bare-soil composites, SRTM-derived topographic variables, and ERA5 meteorological data. SMDFS were generated via percentile reconstruction of multi-temporal moisture indices (MNDWI, NDWI, NDMI) to capture dynamic feedbacks between SOM levels and moisture retention. The ExP-C model fuses expert convolutional networks for spatial contextual extraction from static covariates, pyramid 1D convolutions for multi-scale SMDFS pattern mining, and contrastive learning to bolster feature representations, with transfer learning (pre-training on Chinese data, fine-tuning on U.S. data) enabling cross-regional adaptation. Ten-fold cross-validation yielded superior performance for ExP-C compared to random forest and CNN-LSTM baselines: $R^2 = 0.712$ (RMSE = 6.221 g/kg) in China and $R^2 = 0.554$ (RMSE = 7.693 g/kg) in the U.S. when integrating SMDFS with spatial features, with SMDFS alone boosting $R^2$ by 11-14% on static inputs. Gradient-based attribution confirmed SMDFS and elevation as dominant contributors, underscoring their mechanistic role in SOM variability. Transfer learning further improved U.S. predictions to $R^2 = 0.572$ (RMSE = 7.597 g/kg) using a partial freeze strategy on spatial branches. High-resolution (30 m) SOM maps revealed north-south gradients in both regions, with mean contents of 32.0 g/kg (China) and 36.8 g/kg (U.S.), and low uncertainty (means of 4.03 and 4.79 g/kg, respectively). This framework advances SOM mapping by explicitly modeling moistureSOM feedbacks, offering a robust, transferable approach for monitoring carbon dynamics in global croplands and informing sustainable management.

**ABSTRACT**

Persistent cloud cover presents a fundamental constraint for continuous monitoring of bare soil dynamics through optical remote sensing in perennially cloudy regions. To address this limitation, this study proposes an integrated computational framework that synergistically combines multi-source remote sensing datasets, including Sentinel-1 Synthetic Aperture Radar (SAR) imagery, Harmonized Landsat Sentinel-2 (HLS) surface reflectance composites, and high-resolution topographic derivatives. The methodology advances current approaches by strategically incorporating microwave-based feature descriptors, thereby constructing a multidimensional discriminative feature space through the fusion of optical spectral indices, SAR-derived metrics, and geomorphological parameters. This integrative feature engineering significantly enhances the separability between bare soil and spectrally similar land cover classes. The approach provides a technically sound foundation for precision agriculture planning, spatially explicit soil erosion modeling, and systematic land degradation assessment, establishing an operational paradigm for dynamic soil exposure monitoring in cloud-affected environments.

**ABSTRACT**

Accurate prediction of soil organic matter (SOM) is essential for maintaining soil security and supporting agricultural production. In the field of SOM mapping, convolutional neural networks (CNNs) mainly focus on local receptive fields for feature extraction, lacking attention to global receptive fields, especially in complex landscapes such as hilly regions, where SOM has high spatial heterogeneity and accuracy improvement is difficulty in prediction. This study proposes a highly flexible Receptive Field Fusion Module (RFFM) that can be seamlessly integrated into any CNN architecture. RFFM includes a Global Receptive Field Block (GRFB) and a Local Receptive Field Block (LRFB). GRFB aims to capture global dependencies on feature dimensions, while LRFB focuses on local feature associations. And based on RFFM, a new model for SOM prediction (RFFM-SOMPNet) was proposed, which integrated these two different feature scales to improve the accuracy of SOM prediction. The experiment conducted in the hilly area, Longshan County, Hunan Province, China, shows that RFFM-SOMPNet has better predictive performance, with an $R^2$ improvement of 9.67% compared to the benchmark model. In addition, differences in SOM spatial patterns between concentrated and scattered distribution areas of cropland were discovered, and the reasons for these differences were explored through uncertainty analysis and variable contribution analysis. The results indicate that RFFM can effectively integrate global and local receptive fields, improve SOM prediction accuracy, and provide reliable data support for ensuring soil safety and supporting sustainable agricultural production.

**ABSTRACT**

Agriculture covers 53% of the total land area in the Czech Republic, with the majority of agricultural properties being leased. This raises concerns about soil conservation, as short-term gains may take precedence over long-term soil health. In practice, farmers primarily enhance productivity through fertilization, often without considering key factors such as carbon (C) content, biological activity, and soil compaction. The aim of this study was to develop a soil health index map for the Czech Republic using remote sensing and machine learning techniques. A bare topsoil proxy, derived from satellite data, was combined with spatialized soil properties from four different databases. The generated maps were used to assess three critical soil functions: nutrient storage and cycling (f1), carbon storage (f2), and support for plant growth (f3). These functions were then integrated to generate the soil health index map for the country. The predictive models for C and cation exchange capacity (CEC) outperformed global averages, likely due to the incorporation of bare soil reflectance and a robust dataset. In contrast, the prediction of nutrients such as nitrogen (N), phosphorus (P), and potassium (K) showed lower performance, reflecting their high spatial variability due to land management practices. The soil health index (SHI), calculated from the standardized property maps, ranged from 0.26 to 0.70, with most areas exhibiting intermediate values. Forests and agricultural lands showed similar SHI distributions, indicating limited soil resilience across land uses. This approach effectively captured spatial variability in soil properties and facilitated the assessment of soil functions related to erosion, organic matter depletion, and compaction. These findings offer a comprehensive understanding of soil conditions and provide valuable insights for sustainable land-use planning.

**ABSTRACT**

Wildfires disrupt soil structure and alter microbial diversity, reducing ecosystem resilience and delaying natural recovery. Restoring native soil microbiomes may enhance plant fitness and promote the degradation of toxic combustion by-products such as PAHs and PyOM. To identify key bacterial taxa with potential for microbiome- based remediation, we investigated wildfire-driven shifts in soil bacterial communities across a pine–oak forest in Mexico. Sixteen soil samples were collected from burned and unburned areas representing three post-fire recovery stages. Bacterial communities were characterized using 16S rRNA Illumina MiSeq sequencing and QIIME1, complemented by physicochemical analyses and culture-based isolation followed by MALDI-TOF identification.

Time since wildfire emerged as a major determinant of community composition, with significant variation along pH and elevation gradients. Burned and unburned soils differed in the relative abundance of Actinobacteria and Acidobacteria and showed enrichment of thermotolerant and pollutant-degrading taxa. Although 50% of species were shared between conditions, co-occurrence network analyses revealed higher connectivity in unburned soils, suggesting greater community stability. Pyrophilous genera such as *Massilia*, *Arthrobacter*, and *Blastococcus* were detected, with *Arthrobacter* and *Blastococcus* forming part of the core microbiome and highly connected network modules.

Culture-based analyses yielded 275 bacterial isolates, of which 126 were identified and assigned to 50 species.

Burned soils exhibited higher cultivable diversity than unburned soils. Dominant species included *Achromobacter xylosoxidans*, members of the *Enterobacter cloacae* complex, and *Bacillus cereus*. Notably, several isolated taxa were not detected by amplicon sequencing, highlighting the complementarity of cultivation-dependent and - independent approaches.

Overall, these results emphasize the value of integrating sequencing, network analysis, and culturable microbiome approaches to identify key bacterial taxa for microbiome-based restoration strategies in fire-prone ecosystems.

**ABSTRACT**

Carbon in wetlands is a critical component of the terrestrial carbon pool in the global carbon cycle. Accurate quantification of wetland soil organic carbon (SOC) is essential for sustainable wetland management and climate change mitigation. However, this effort is often hampered by the inaccessibility of wetlands and high economic and labor costs associated with data acquisition. The advent of visible and near–infrared (Vis-NIR) spectroscopy offers a time- and cost-effective method for monitoring SOC content. Considerable efforts have been directed toward estimating wetland SOC using Vis-NIR spectroscopy. However, great differences were reported for the performance of different predictive strategies, which pose confusion in the choice of methods when using Vis-NIR spectroscopy to estimate SOC. Therefore, this study aims to improve the in-situ spectral estimation accuracy of wetland SOC by testing and evaluating 240 optimization strategies which integrate different pre-treatment technologies, moisture removal algorithms, spectral feature selection methods. Our findings indicate that the optimal strategy involved the combination of first-order derivative (1stD), external parameter orthogonalization (EPO), modified greedy feature selection (MFGS), and one-dimensional convolutional neural network (1D-CNN), yielding $R^2$, RPD, RMSE values of 0.94, 4.15, and 1.09 g/kg, respectively. For pre-treatment technologies, 1stD outperformed Savitzky-Golay (SG) and log(1/reflectance) (Log(1/R)). EPO emerged as the optimal moisture removal algorithm, effectively reducing the interference of moisture and other environmental factors. Among spectral feature selection methods, the competitive adaptive reweighting algorithm (CARS) outperformed Boruta, MFGS, and interval random frog (IRF). In terms of prediction models, the 1D-CNN model significantly outperformed partial least squares regression (PLSR) and random forest (RF), with markedly higher accuracy (averaged $R^2$ = 0.83, RPD = 2.74, RMSE = 1.76 g/kg). Findings from this research could guide future studies in selecting the optimization strategies to more accurately estimate wetland SOC via Vis-NIR spectroscopy.

# Spatio-temporal fusion–based analysis of soil salinization dynamics in the Ningxia–Inner Mongolia Yellow River Irrigation District (2000–2025)

**Qiding. Ding, Huayu. Huang, Junhua. Zhang***

*College of Ecology and Environmental Science, Ningxia University, Yinchuan 750021, China)*

**ABSTRACT**

Soil salinization poses a severe challenge to global agricultural productivity, ecosystem resilience, and the sustainable use of regional resources. Under the combined impacts of climate change and unsustainable land-use practices, both primary and secondary salinization processes driven by natural and anthropogenic factors have continued to intensify, seriously threatening food security and soil health in arid regions. Existing studies largely rely on single-source remote sensing data and short-term inversion models, which are insufficient to support long-term dynamic analyses of soil salinity. To address this limitation, this study developed a deep learning–based multi-source remote sensing data fusion framework that synergistically integrates MODIS and Landsat 5/7/8/9 imagery to generate surface reflectance datasets with high spatio-temporal consistency. Combined with field-measured data, soil salinity inversion models based on Support Vector Machines (SVM), Random Forests (RF), and Convolutional Neural Networks (CNN) were constructed to systematically map soil salinity dynamics and analyze evolutionary trends in the Ningxia–Inner Mongolia Yellow River Irrigation District from 2000 to 2025.The results indicate that soil salinity in the study area ranges from 0.39 to 17.38 $g \cdot kg^{-1}$, exhibiting pronounced spatial heterogeneity. The deep learning–fused imagery outperformed the original datasets in both spectral fidelity and spatio-temporal continuity, effectively balancing temporal consistency required for long-term monitoring with the preservation of spatial detail. Among the models, the CNN achieved significantly higher inversion accuracy than the RF and SVM models. The mapping results further reveal a continuous expansion of non-saline soils, a marked reduction in severely salinized soils and saline soils, and stage-wise fluctuations in the areas of slightly and moderately salinized soils, reflecting the notable effectiveness of salinity control measures in the region. Overall, soil salinity in the Ningxia–Inner Mongolia Yellow River Irrigation District has shown a declining trend over the past two decades, although significant local fluctuations persist. This study demonstrates the advantages of deep learning–based fusion frameworks for long-term dynamic monitoring of soil salinity and provides methodological support for precision management of saline–alkali lands and the development of soil salinity prediction models at the regional scale.

# SWRCI: A Novel Remote Sensing Index for Soil Water Retention Capacity

**Linghua Meng[1*], Ya Chen[1]**

[1] *Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Changchun 130012, China*

*menglinghua@iga.ac.cn

**ABSTRACT**

Soil water retention capacity (SWRC) is a key indicator affecting crop growth and ecosystem water dynamics. To address the inefficiency of traditional field work, this study selected Youyi and Heshan farm in Heilongjiang Province as the study area, and constructed the soil water retention capacity index (SWRCI) based on the time series sensor soil moisture and the 2020-2025 Sentinel-2A Normalized Difference Water Index (NDWI). Second, time series NDWI from snow cover to bare soil was selected, and the mathematical model was used to fit the time series sensor soil moisture and NDWI; Then, the characteristic parameters of the time series were extracted to construct the SWRCI, and validated by the measured sensor soil moisture and measured field capacity (FC). Finally, we analyzed the spatial patterns of the SWRC. Results showed that the time series NDWI and sensor soil moisture show significant consistent with the soil water retention curve (SWRTC) trends, reflecting different soil degradation types. And they were effectively described by an exponential decay fitting model (EDFM) ($R^2$=0.84–0.99). The SWRCI could effectively indicate the degree of soil degradation and was significantly correlated with soil organic matter ($p<0.001$, R=0.78–0.84), texture (sand: $p<0.001$, R=−0.8–−0.75, silt and clay: $p<0.001$, R=0.71–0.79), and crop yield ($p<0.001$, R=0.78–0.79). Furthermore, the performances of SWRCI in quantifying soil degradation have been validated across the two study areas. The study offers new tools for precision water management and degraded-soil restoration, with strong theoretical and practical value.

*E-mail Address: BS20243030382@cau.edu.cn.

**ABSTRACT**

Rapid assessment of soil available nutrients is essential for precision agriculture. The proximal sensors offer promising technologies for soil available nutrients estimation. However, the prediction accuracy of AP and AK remains challenging for both single and multi-sensor fusion approaches due to low concentrations and weak spectral features. To further improve fusion model accuracy, this study, integrating mid-infrared (MIR) and portable X-ray fluorescence (pXRF) spectroscopy, systematically evaluated the impact of various preprocessing methods and band-selection algorithms on soil nutrient prediction models in Hebei Province, China. Four types of models were compared: (1) single sensor; (2) direct concatenation (DC); (3) feature-level fusion (FU) using sCARS or a novel Adaptive Importance-driven Feature Refinement with Correlation (AIFC) algorithm; and (4) decision-level fusion employing Granger-Ramanathan Averaging (GRA) and Bayesian Model Averaging (BMA). Partial least squares regression (PLSR) and Cubist were employed.

Results showed that sensor fusion significantly improved prediction accuracy. The feature-level fusion Cubist model for AP achieved $R^2_V = 0.83$, outperforming single sensors ($0.68 \leq R^2_V \leq 0.73$). Decision-level fusion models for AK elevated predictions from $R^2_V < 0.65$ to 0.68. Critically, SNV preprocessing proved essential for PLSR fusion, ensuring balanced sensor contributions (11.05–88.95%), while other preprocessors biased predictions toward pXRF. The AIFC algorithm enhanced AP prediction to $R^2_V = 0.83$ using only 8.40% and 0.93% of MIR and pXRF bands, outperforming single sensor ($R^2_V = 0.73$) and DC models ($R^2_V = 0.78$). For SOM and TN, MIR alone achieved $R^2_V = 0.89$, equal to fusion models.

In summary, this study highlighted the necessity of SNV in constructing feature-level fusion PLSR models and demonstrated that sensor fusion of MIR and pXRF could be an alternative approach for the accurate prediction of AP and AK.

# A Dataset-Based Statistical Comparison and Fusion of Gamma-Ray and Visible-Near-Infrared Sensing Technologies for Soil Texture Prediction

**Jiang Liu[1*], Abdul Mounem Mouazen[1]**

[1] *Department of Environment, Faculty of Bioscience Engineering, Ghent University, Coupure Links 653, 9000, Gent, Belgium*

*E-mail Address of Presenting Author: jiang.liu@ugent.be

**ABSTRACT**

Soil texture plays a crucial role in environmental and agricultural applications. Traditional methods for soil texture determination are labor-intensive, costly, and time-consuming. This study compares the performance of proximal gamma-ray and vis-near-infrared (vis-NIR) sensors and the potential of fusing of these two technologies for soil texture measurement. A total of 197 soil samples were collected from 11 agricultural fields in Belgium and France and analyzed using a gamma-ray sensor (0-3 MeV), a fiber-optic vis-NIR sensor (305-1700 nm), and a micro-NIR sensor (2000-2450 nm). Gamma-ray data were processed using both the region of interest (ROI) and gamma-ray full spectrum (GFS) methods. The dataset was randomly divided into a training set (75 %) and a test set (25 %). Partial least squares regression (PLSR), support vector regression (SVR), and random forest (RF), were used to develop predictive models for clay, silt, and sand contents. Early-level, feature-level, and decision-level fusion methods were applied for fusing the two sensing technologies. The results indicate that micro-NIR demonstrated superior performance in clay prediction, while gamma-ray spectroscopy was more effective for silt and sand prediction. Fusion greatly improved the cross-validation in most cases, indicating reduced potential of model over/under-fitting. Feature-level (RF features of micro-NIR + ROI of gamma-ray) modeled with SVR reached the best clay prediction [coefficient of determination in prediction ($R_P^2$) = 0.89, root mean squared error of prediction ($RMSE_P$) = 2.43 %], decision-level fusion with stacking methods achieved highest prediction accuracy and for silt ($R_P^2$ = 0.91 and $RMSE_P$ = 7.05 %), and sand ($R_P^2$ = 0.92 and $RMSE_P$ = 7.75 %). These findings provide valuable guidance for selecting either a single sensing technology or a fused sensing approach for accurate field soil texture estimation.

# Measuring Soil Health Using Technologies Across Scales

**Asim Biswas[1]***

[1] *School of Environmental Sciences, University of Guelph, Guelph, ON Canada N1G 2W1*

*biswas@uoguelph.ca

**ABSTRACT**

Soil health underpins food security, climate resilience, and ecosystem services, yet its measurement remains constrained by cost, labour, and limited spatial and temporal resolution. Recent advances in sensing technologies offer unprecedented opportunities to transform soil health assessment from discrete point, plot-based measurements to continuous, scalable, and decision-ready information. This talk synthesizes advances in soil health monitoring across scales, with a primary focus on proximal soil sensing while explicitly extending the framework to areal and remote sensing to demonstrate scale transfer. The presentation will provide an overview of key technologies I have been developing and applying, including image-based soil analysis, visible–near infrared (VNIR) spectroscopy, electromagnetic induction sensing, in situ profile measurements, drone-based multispectral imaging, and satellite observations. These approaches enable the rapid estimation of physical, and chemical soil health indicators from the sample and profile scale to fields, landscapes, and regions. Using selected case studies, I will illustrate how high-resolution proximal measurements can be used to calibrate and constrain models at coarser spatial scales, allowing soil health information to be meaningfully transferred across sensing domains. By explicitly linking proximal, areal, and remote sensing observations through scale-aware modelling and data integration, this work demonstrates how soil health monitoring can move beyond isolated measurements toward integrated, multi-scale frameworks. Such approaches are essential for supporting precision management, regional soil health reporting, and policy-relevant monitoring systems.

## ABSTRACT

We provide an overview of the accuracy of soil property predictions using the most common proximal sensing (PSS) techniques in precision agriculture (PA), both standalone and in combination with one another or with environmental covariates. Based on 114 scientific papers, we evaluate the accuracy of soil property estimates by calculating the normalized root mean square error (NRMSE) using RMSE values and the range of the predicted soil property. Soil properties, PSS techniques, covariate types, and the model employed for predictions are the factors used to sort the accuracy results. We estimate PSS service costs using both the literature and a market study with questionnaires from private companies in PA. Our analysis indicates that diffuse reflectance spectroscopy (DRS) can estimate the greatest number of soil properties with high accuracy among the PSS techniques. Popular DRS applications include determining soil organic matter, nutrients, and soil texture. X-rayfluorescence (XRF) is the second-most popular technique for estimating soil properties. XRF is widely used in the field to determine elemental concentrations. On-the-go techniques such as electromagnetic induction (EMI) or gamma-ray spectroscopy (γ-ray) yield lower accuracy than point-based techniques. They are widely used by companies because they can delineate PA management zones in the field and are suitable for on-the-go mapping of soil properties such as mineralogy, texture, salinity, water content, cation exchange capacity, and soil depth. The combined use of PSS techniques generally doesn't outperform the singular application, although the number of samples collected for calibration and the specific combinations of sensors, covariates, and modeling techniques, when correctly applied, may enhance the predictions of soil properties using PSS techniques applied singularly. These outcomes tend to depend on local site characteristics.

According to data, the estimated cost of surveying a hectare with PSS oscillates between 15.5€/ha and 130€/ha, whereas our company survey yielded an interval of 142-362€/ha. Price variability was influenced by personnel costs, fieldwork, data and reporting, sample analysis, and equipment. Increases in final prices can be attributed to accessibility and difficulties related to fieldwork and travel to the area of interest. This work aims to serve as a References for the adoption of sensing technologies by farmers, policymakers, and companies, providing insights into the suitability of different PSS techniques for soil mapping, their associated costs, and what is available in the market. We foresee that PSS will become the standard approach for producing high-resolution maps and affordable soil property information in the future.

**ABSTRACT**

Soil drainage class is a major source of landscape variability in Canada and the primary criterion for differentiating soil series in the province of Ontario. Drainage differences are typically governed by topographic relief, which controls surface water redistribution, and depth to groundwater, but may also arise from internal soil stratifications. Magnetic susceptibility (MS), a measure of the extent to which a material is magnetized, is a well-established indicator of soil mineralogy due to the strong MS contributions of Fe-bearing minerals. Because the nature of Fe oxides is sensitive to redox conditions—with $Fe^{3+}$ phases exhibiting substantially higher MS than $Fe^{2+}$—MS can be used as a proxy for assessing soil drainage. This study employed frequency-domain electromagnetic induction (EMI) sensors (Dualem-21 and EM38-MK4) to map magnetic susceptibility (MS) and apparent electrical conductivity (ECa) across three topographically variable sites in Ontario. Soil cores were collected at 150 points within the three study sites and examined for redoximorphic features (i.e. gleying and mottling), to classify drainage status. Laboratory measurements of volume and mass-specific MS were obtained using Bartington MS2C and MS2B sensors on core and dried samples. Our initial analysis is focused on understanding the relationship between lab-measured MS on soil cores, inverted EMI-MS measurements and redoximorphic features. Given the speed, precision, and cost-efficiency of EMI methods relative to conventional field-based classification, EMI-derived MS offers strong potential for rapid delineation of soil drainage classes across agricultural landscapes.

# A comparative study of four color measurement methods for soil color identification and related properties prediction

**Yuanyuan Du[1*], Rong Zeng[1*]**

[1] *School of Geographic Science, Nanjing University of Information Science and Technology, Nanjing 210044, China*

*rzeng@nuist.edu.cn

**ABSTRACT**

Soil color serves as a comprehensive indicator of soil composition and intrinsic properties and can be used to predict these properties. The identification of soil color by proximal sensing varies among and even within color measurement methods. In addition, several color space models can be used to quantify color. This poses the question as to the difference between soil color measurement methods in different color spaces, the property predictions from these, and their optimal combination. A total of 200 soil samples from China, 80 from Guizhou Province and 120 from Hunan Province, were used to address this question. The color of these samples was measured by four different methods: subjective visual estimation, a smartphone, a Nix Pro2 colorimeter and an ASD spectrometer. The color difference in CIEL*a*b* color space, defined as (ΔEab), between these methods was quantified using the National Bureau of Standard (NBS) unit. Five color space models, including RGB, HIS, CIEL*a*b*, CIEL*c*h*, and CIEL*u*v*, were used to quantify soil color parameters defined by each model. These parameters were then used to predict the color-associated properties soil organic matter (SOM) and free iron concentrations (FI). Stepwise multiple linear regression (SMLR), back propagation neural network (BPNN) and partial least squares regression (PLSR) models were built to make these predictions. The color difference between the Nix Pro2 and smartphone was the smallest (ΔEab = 2.66 NBS, considered “noticeable”), while significant systematic differences were found between ASD and the other methods (ΔEab 23.48 to 25.51 NBS, “very much”). Using the visible spectra measured by the ASD as input to the PLSR model as a baseline, the ratio of performance to interquartile range (RPIQ) range for SOM prediction by other sensors and models varied from 2.90 to 3.43, while for FI, it ranged from 3.07 to 3.93. Different methods had quite different prediction performances. The ranks were Nix Pro2 > smartphone > ASD > subjective visual estimation, PLSR > BPNN > SMLR for SOM, and smartphone > Nix Pro2 > ASD > subjective visual estimation, PLSR > SMLR > BPNN for FI. Brightness-related color parameters (R, h* and L*) are recommended for SOM prediction, and yellow- and red- related parameters (S and b*) for FI prediction. The Nix Pro2 and smartphone are recommended as portable and cost-effective instruments for proximal soil sensing.

# Comparison of mid–infrared and visible/near–infrared spectroscopy of moist–intact cores and dry–ground soils for soil property prediction

**Wenjun Ji[1*], Jianxin Yin[1], Baoguo Li[1] José A.M. Demattê[2],Tianyu Miao[1],Yuanfang Huang[1],Tusheng Ren[1], Songchao Chen[3] , and Zhou Shi[3]**

**ABSTRACT**

Mid–infrared spectroscopy (MIR) has shown great potential in soil health monitoring, but it is typically confined to laboratory measurements on dry–ground soils. To systematically evaluate the predictive performance of different spectra for key soil health indicators across the 0–100 cm profile in the Northeast Black Soil (Mollisols) region of China, this study assessed attenuated total reflectance (ATR) MIR spectroscopy on moist–intact soil cores (0–100 cm) and compared it with visible and near–infrared (VNIR) spectra on moist cores and with conventional dry–ground MIR and VNIR. Forty–nine cores (490 subsamples) were collected from Lishu County, Jilin Province, China. Organic matter (OM), total nitrogen (TN), available nitrogen (AvN), available phosphorus (AvP) and cation exchange capacity (CEC) were measured, and models were built using partial least squares regression (PLSR), support vector machines (SVM) and long short–term memory networks (LSTM). Validation strategy strongly affected estimated generalization: sample–based splits were optimistic, whereas core–based splits provided realistic performance. Under core–based validation, moist–intact ATR–MIR predicted OM ($R^2$ = 0.59, RMSE = 4.90 g/kg), TN ($R^2$ =0.51, RMSE = 0.29 g/kg) and CEC ($R^2$ = 0.75, RMSE = 3.60 cmol/kg), while AvN and AvP were not consistently predictable. Across spectra, performance ranked moist–intact MIR<moist–intact VNIR<dry–ground VNIR<dry–ground MIR. LSTM performed best with dry–ground MIR, whereas PLSR provided the most robust baseline across spectra. Models calibrated only on shallow layers (0–40 cm) did not stably predict deeper properties, reinforcing the need for full–profile measurements. Overall, while dry–ground MIR yielded the highest accuracy, the moist–intact MIR approach provided acceptable accuracy, acquiring molecular fingerprinting information without labor–intensive drying and grinding. ATR–MIR on moist–intact cores provides a foundation for extending MIR toward field–relevant workflows for rapid assessment of soil health indicators relevant to nutrient management and environmental protection.

# Dynamic inversion of soil salinity in farmland across the Hetao Plain of China based on a spatiotemporal fusion algorithm (2000–2024)

**Huayu Huang [1], Qidong Ding[1], Junhua Zhang[1], Lingbin Yang[1], Keli Jia[2]**

**ABSTRACT**

Accurate monitoring of the spatiotemporal dynamics of soil salinity is imperative for achieving sustainable utilization of limited farmland resources, especially in arid regions. However, current studies disproportionately focused on short-term soil salinity inversion with a single remote sensing data source, lacking comprehensive analysis of long-term evolution. The aim of this study was to investigate the spatiotemporal patterns of soil salinity in farmland of the Hetao Plain in northern China across seven stages (2000–2024) based on high-precision mapping. A deep learning framework for multi-source remote sensing data fusion was proposed to fuse MODIS images with Landsat 5/7/8/9 and Sentinel-2 images, generating two high-spatiotemporal-resolution surface reflectance datasets. Three inversion models of soil salinity were developed based on machine learning algorithms by incorporating salinity indices, environmental covariates, and ground-truth measurements. The measured soil salt content ranged from 0.39 to 17.38 $g \cdot kg^{-1}$, indicating pronounced spatial heterogeneity of salinity. Deep learning-based image fusion successfully balanced temporal continuity and spatial detail across different sensors. The convolutional neural network achieved higher accuracy than two conventional machine learning models (support vector machine and random forest), yielding the greatest $R^2$ value for the validation set (0.884). Digital mapping results revealed that the area of non-saline soils continued to expand over time. While periodic variations occurred in the areas of slightly and moderately saline soils, there were noticeable reductions in the areas of heavily and extremely saline soils. Transfer matrix analysis revealed stepwise transitions of soil salinity between adjacent classes, indicating declines in salinization levels. The findings indicate that soil salinity in farmland of the Hetao Plain has decreased over the past two decades, despite substantial variations in localized areas. This study provides robust methodological support for large-scale monitoring of farmland salinization and the development of soil salinity prediction models.

**ABSTRACT**

Accurate and effective monitoring of potentially toxic elements (PTEs) in soil across vast regions is crucial for environmental modeling and public health. While remote sensing (RS) technology provides a promising approach by detecting soil spectrum, dense and persistent vegetation cover in subtropical agricultural areas hinders acquisition of bare soil signals, limiting soil PTEs monitoring. To address this challenge, the present study proposed an innovative method for monitoring soil arsenic (As) content by using vegetation characteristics retrieved from RS data as proxy variables, given soil-vegetation interactions. The method was evaluated in a densely vegetated cropland of southern China, where 104 surface soil samples were collected. Vegetation in formation was extracted both individually and synergistically using time-series Sentinel-2 multispectral and Sentinel-1 synthetic aperture radar (SAR) images throughout the entire growing season, and an unmanned aerial vehicle (UAV) hyperspectral image during the crop maturity. Multiple machine learning algorithms, including Random Forest, Support Vector Regression, CatBoost, and Stacking were applied to model the relationship be tween soil As and vegetation variables. The SHapley Additive exPlanation (SHAP) technique was introduced for identifying key variables and corresponding thresholds indicating significant accumulation of soil As. Results showed that time-series satellite-multispectral images outperformed other single RS data types in terms of pre diction accuracy. Moreover, the synergy of optical and SAR images significantly improved model accuracy. Particularly, the combination of time-series satellite multispectral and SAR data using the stacking algorithm achieved the best results, with a coefficient of determination (R 2 ) of 0.71 and a root mean square error (RMSE) of 20.22 mg/kg. Key predictive variables included red-edge vegetation index (RENDVI3) on August 7 and May 26, and the blue band on October 26, with values below 0.018, 0.013 and 0.052, respectively, indicating the As accumulation in soil. In summary, the proposed method of using multiple RS data to retrieve vegetation char acteristics for inferring soil PTEs in densely vegetated areas was convenient, cost-effective, and reliable, offering new insights and technical support for environmental monitoring.

# Mapping mollic epipedon thickness via ground-penetrating radar based on the combined method of Variational Mode Decomposition and Average Envelope Amplitude

**Haipeng Lu[1], Xiangming Zhu[1]*, Wenjuan Zheng[2], Bin Zhang[2] Tianhao Wang[1], Yu Zhang[1], Meiling Fu[1], Enhua Ran[1]**

**ABSTRACT**

Accurate monitoring of mollic epipedon (ME) thickness, especially in sloping farmland, is of great significance for preventing soil erosion and promoting sustainable agriculture in Mollisol area. Ground penetrating-radar (GPR) provides an approach for continuously and non-destructively acquiring the information of soil horizon thickness. However, traditional GPR signal processing methods are susceptible to noise interference when locating soil horizon interfaces. Additionally, it remains challenging to accurately estimate the electromagnetic wave velocity due to the high spatial heterogeneity of natural soil. In this study, we proposed a combined GPR signal processing method of Variational Mode Decomposition (VMD) and average envelope amplitude (AEA), termed VMD–AEA, to investigate the ME thickness. And a GPR survey of 1.5 ha sloping farmland in the Mollisol region of Northeast China was conducted to verify the method. The noise of GPR signals was reduced using the VMD method, and then the instantaneous frequency of the denoised signal was extracted via the Hilbert transform. Subsequently, the maximum value of the instantaneous frequency was picked up through peak detection to automatically locate the ME interfaces. The results showed that the automatically located ME time-domain interfaces matched the actual interfaces marked by pre-buried steel pipes. The time-domain positions of the ME interface along survey line 1 fluctuated around 10 ns. In addition, to continuously acquire the wave velocity, a dielectric constant model was established based on the correlation between the AEA values of GPR signal and the measured dielectric constant. As expected, there was a significant negative correlation between the dielectric constant and the AEA value ($R^2 = 0.92$). The ME thickness obtained by the VMD–AEA method was consistent with the measured thickness through soil profile method, with the absolute error and relative error within 5 cm and 10%, respectively. This study proposed a novel method for automatically, continuously, and accurately obtaining the ME thickness and demonstrated its potential in the protection and utilization of Mollisol.

**ABSTRACT**

Rapid and accurate acquisition of soil property is crucial for precision agriculture, ecological protection, and scientific research. This study proposes and evaluates two hybrid deep learning frameworks to enhance the effectiveness of visible-near-infrared (vis-NIR) spectroscopy in soil property estimation.

Study 1: To address the challenge of simultaneous multi-property estimation, this paper constructed a model based on the Multi-gate Mixture-of-Experts (MMoE) network. Utilizing vis-NIR spectral data from 17,272 mineral soil samples in the LUCAS database, the model achieved high-precision simultaneous estimation of ten soil properties. Compared to the traditional shared-bottom multi-task convolutional neural network, MMoE can effectively distinguish and extract both common and unique spectral features of different properties, reducing the RMSE by 3%–48% and increasing the $R^2$ by 1%–119%. The study also found that a data augmentation technique stacking multiple spectral pre-processing methods significantly improved model performance (reducing RMSE by 14%–28%), while the Competitive Adaptive Reweighted Sampling (CARS) method for extracting feature spectra showed limited effectiveness in modeling.

Study 2: To mitigate the impact of in-situ spectral measurement errors and optimize model architecture, we developed an automated optimization framework for hybrid deep learning models based on Bayesian Optimization combined with Hyperband (BOHB). Taking the estimation of soil organic matter using 670 soil samples from the Nanning region of China as a case study, a systematic comparison was conducted between two hybrid architectures: CNN-LSTM and LSTM-CNN. The results indicate that when the sample size is below 600, the advantage of hybrid models is not pronounced. However, after automated hyperparameter optimization by BOHB, their accuracy significantly surpasses that of single deep learning models, Partial Least Squares Regression, Random Forest, and other traditional methods.

In summary, the MMoE and the automated optimization framework for hybrid deep learning models developed in this study provide methodological References for the efficient and accurate estimation of soil properties.

**ABSTRACT**

Conventional laboratory-based soil analysis, though accurate, is often time-consuming, labor-intensive, and expensive, especially when large spatial datasets are required for soil fertility evaluation and soil health assessment. In this context, proximal soil sensing using visible–near infrared (VIS–NIR) and mid-infrared (MIR) spectroscopy has emerged as a rapid, non-destructive, and environmentally sustainable alternative for soil characterization. The present investigation was undertaken to evaluate the potential of proximally sensed soil spectral data as a reliable proxy for conventional soil analysis, with special emphasis on hyperspectral modeling using VIS–NIR and MIR regions. The study was conducted in the Varanasi region of eastern India, representing diverse land-use systems and soil-forming environments. A total of 300 geo-Referencesd surface soil samples (0–15 cm) were collected from rice wheat cropping systems and upland vegetable growing areas following standard sampling protocols. Soil samples were processed and analyzed for key chemical attributes such as pH, electrical conductivity (EC), organic carbon (OC), available phosphorus and potassium using standard laboratory methods. Spectral reflectance measurements were recorded under controlled laboratory conditions. VIS–NIR spectra (350–2500 nm) were acquired using a FieldSpec Pro spectroradiometer, while MIR spectra (2500–25,000 nm) were obtained using an Alpha-MIR spectrometer. Various spectral preprocessing techniques were evaluated; however, raw reflectance and absorbance-transformed spectra generally provided comparable or superior predictive performance across soil properties After removal of spectral outliers, 280 soil samples were used for model development. Prediction models were developed using Partial Least Squares Regression (PLSR), Random Forest, Support Vector Regression, and Multivariate Adaptive Regression Splines, with 70% of the data used for calibration and 30% for validation. Among the modeling approaches, PLSR consistently showed superior performance for simultaneous prediction of multiple soil properties. VIS–NIR spectroscopy performed better for pH, EC and available potassium whereas MIR spectroscopy showed higher accuracy for organic carbon and available phosphorus. Overall, the study demonstrates that VIS–NIR and MIR spectral data can serve as reliable proxies for conventional soil laboratory analysis. The complementary nature of these spectral regions highlights their potential for rapid, cost-effective, and large-scale soil assessment, supporting precision agriculture, soil health monitoring, and sustainable land management.

**ABSTRACT**

The alkalized horizon is a critical barrier layer in saline-alkali soils, directly governing root development and water-salt dynamics. Accurately identifying and quantifying its spatial distribution remains a major challenge due to its high heterogeneity. This study employed Ground Penetrating Radar (GPR) combined with the CatBoost machine learning algorithm to predict the spatial distribution of the alkalized horizon in typical soda saline-alkali soils of the Songnen Plain. Data were collected along ten survey lines containing 21 validation points. GPR signal features were extracted using Full Waveform Inversion (FWI) and wavelet transform, with key features subsequently selected by integrating CRITIC, Random Forest (RF), Mutual Information (MI), and Coefficient of Variation (CV) methods. Machine learning was applied to quantify the relationships between these key radar features and soil pedogenic characteristics. Model validation using the 21 independent points yielded robust performance, with all lines achieving a Kappa coefficient > 0.5 and an AUC value > 0.7. SHAP analysis revealed that dielectric constant and pedogenesis-related features were the dominant factors controlling the spatial variation of the alkalized horizon. This integrated GPR-ML framework provides an efficient, reproducible solution for the intelligent mapping of saline-alkali horizons. It also offers a valuable methodological References for the spatial modeling and characterization of subsurface layers using GPR, demonstrating significant application potential for saline-alkali land assessment and cultivated land quality evaluation.

# Quantitative Monitoring and Inversion of Soil Moisture Content Based on Ground Penetrating Radar: Progress, Methods, and Prospects

**Ping Wang**[1*]

[1] *School of Geography and Tourism, Qufu Normal University, Rizhao, China*

*wpqfnu@qfnu.edu.cn

**ABSTRACT**

Soil moisture content (SMC) is a critical physical parameter that regulates the hydrological cycle, agricultural productivity, and ecosystem health. Ground Penetrating Radar (GPR) can indirectly and rapidly invert soil dielectric constant by analyzing the dynamic characteristics (such as wave speed, amplitude, and frequency) of electromagnetic wave propagation in the subsurface medium, thus enabling the estimation of SMC. This technique effectively bridges the spatial scale gap between point-scale measurements and satellite remote sensing observations. The crux of GPR inversion for SMC lies in establishing a reliable physical relationship between the volumetric water content of soil and its dielectric constant, which is primarily controlled by soil moisture. Based on different data acquisition methods and signal processing strategies, mainstream inversion approaches can be categorized into several types: methods based on wave speed/travel time analysis, methods utilizing dielectric constant-water content relationship models, methods based on amplitude attenuation characteristics, methods based on spectral analysis, and integrated methods that couple hydrological models, fuse multi-physical field data, and collaborate with remote sensing data. However, GPR still faces several key challenges in the quantitative inversion of SMC. Firstly, soil dielectric characteristics are not only influenced by moisture content but also significantly depend on various factors such as soil texture, bulk density, clay mineral composition, organic matter content, salinity, and temperature. Secondly, the uncertainties in GPR inversion results stem from several complexities, including data acquisition noise, limitations of the inversion algorithms, physical model mismatches, and the spatial heterogeneity of SMC itself. Additionally, scale matching and data fusion present challenges in practical applications, especially regarding how to derive spatial averages of SMC that effectively represent remote sensing pixel scales, which requires further methodological exploration. Currently, research in this field is gradually shifting from method development to enhancing accuracy, quantifying uncertainty, deeply integrating multi-source data, and optimizing solutions for specific application scenarios. GPR technology is poised to provide solid technical support for achieving more precise and intelligent monitoring and management in areas such as sustainable water resource management, food security production, resilience enhancement of infrastructure, and ecological environmental protection.

# Prediction of soil organic matter using visible–near-infrared spectroscopy combined with textural hand-feel determination

**ABSTRACT**

Timely and accurate estimation of soil organic matter (SOM) is vital for monitoring soil fertility and enabling precision management. This study investigates how combining soil texture data with visible and near-infrared (Vis-NIR) spectroscopy can improve SOM prediction under both laboratory (dry) and in-situ (moist) conditions. We also identify which soil properties cause the most significant differences between dry and moist spectral readings. Four modeling strategies were compared: 1) Pure Spectra (using Vis-NIR data alone), 2) Texture Class and 3) Texture Merged (integrating quantitative clay, silt, and sand content), and 4) Texture Dummy (integrating categorical texture classes determined by hand feel). We used the Cubist algorithm to assess the contribution of different soil properties, while Partial Least Squares Regression (PLSR) and Random Forest (RF) models were used for SOM prediction. Results show that soil texture was the most significant factor driving the differences between the moist and dry spectra. Texture was also the primary variable explaining the prediction errors (residuals) when using spectra alone. Critically, incorporating simple, field-assessed texture data via the Texture Dummy strategy significantly improved SOM prediction accuracy compared to models relying on pure spectra, with the highest R2 increasing from 0.65 to 0.78 and from 0.79 to 0.86 and the root mean square error decreasing from 5.73 to 4.56 g kg−1 and from 4.47 to 3.62 g kg−1 for wet and dry samples, respectively. The Texture merged strategy provided a modest improvement (R2 increasing from 0.63 to 0.66 using in situ spectra), while the Texture class strategy showed the lowest performance, with slightly reduced R2 values for both dry and in situ spectra. The accuracy achieved using the Texture dummy strategy with in situ spectra (R2 = 0.76, LCCC = 0.86) was comparable to that of the general model developed from laboratory spectra (R2 = 0.79, LCCC = 0.88). Our findings demonstrate that incorporating the Texture class determined by hand-feel can effectively guide spectral techniques, enhancing the potential of vis–NIR spectroscopy in rapid estimation of SOM. However, further verification is needed using soils from a wider range of areas and larger spectral libraries, as well as other spectroscopic techniques across different wavelength ranges.

# The use of low-cost spectrometers to predict key soil properties for digital soil mapping in South Sumatra, Indonesia

**Astriana Rahmi Setiawati[1*], Budiman Minasny[1], Wartini Ng[1], Yin-Chung Huang[1]**

[1] *School of Life and Environmental Sciences & Sydney Institute of Agriculture, The University of Sydney, NSW 2006, Australia*

*aset0731@uni.sydney.edu.au

**ABSTRACT**

Detailed digital soil mapping requires dense soil data and observations. However, it is labor-intensive and time-consuming to analyse many soil properties. While the advent of visible and near-infrared (Vis-NIR) spectroscopy offers a time- and cost-effective approach for measuring soil properties, the use of alternative lower cost Vis-NIR spectroscopy for soil properties prediction in digital soil mapping remains limited. This study aims to test the quality of lower-cost Vis-NIR spectrometers in estimating key soil properties in the humid tropical region. We collected soil samples from 291 sites, each with three depths (0-10, 10-20, and 20-40 cm) from Central Lampung, Indonesia based on *k-means* clustering of environmental covariates. We selected 58 sites (174 soil samples) from all clusters as data set for chemical-physical soil analysis and spectra calibration. We tested two emerging spectrometers which are available at a lower cost: a Vis-NIR spectrometer (350-1020 nm) and a NIR-SWIR (900-2500 nm). The samples were scanned under two conditions: field moisture and ground and air-dried. As a comparison, we used the ASD spectrometer (350-2500 nm). The data set was randomly split by sites into 70% training and 30% as test set. We applied Savitzky-Golay smoothing and a second-order polynomial for preprocessing. We investigated several soil properties predictions namely organic carbon, pH, sand, and clay. Prediction models were constructed with partial least squares regression (PLSR) and Cubist tree model. In general, the Vis-NIR-SWIR spectra perform quite good across all properties. The $R^2$ of PLSR ranges from 0.38 to 0.67 for Vis-NIR, 0.50 to 0.67 for NIR-SWIR, as compared to 0.62 to 0.75 for ASD. Cubist model performed slightly better for several properties and conditions. Our findings indicate the prediction of lower-cost Vis-NIR-SWIR spectrometers both under field and dried-sieved condition is comparable to ASD spectra and can be used to estimate soil properties for soil mapping in humid tropical regions.

[3]*Department of Earth & Environmental Sciences, KU Leuven, Belgium*

*ranandrianina@gmail.com

**ABSTRACT**

Stable isotope analyses, particularly those involving carbon and nitrogen ($\delta^{13}C$, and $\delta^{15}N$), provide valuable insights into soil organic matter and nitrogen dynamics and pathways. Such studies are essential for understanding ecosystem functioning by tracing vegetation changes over time through the $\delta^{13}C$ and $\delta^{15}N$ soil profiles. In Madagascar, such studies under open ecosystem areas (OEA) are crucial towards further effective reforestation guidance. However, isotopic measurements remain challenging due to the lack of isotope ratio mass spectrometer (IRMS) infrastructure and the high cost of analyses. To overcome these limitations, the use of spectroscopy techniques either in mid-infrared (MIR) or near-infrared (NIR) could offer a rapid and cost-effective alternative method for future investigations. This study aims to evaluate the potential of MIR and NIR spectroscopy to predict $\delta^{13}C$ and $\delta^{15}N$ values in OEA tropical soils of Madagascar.

Soil samples (n = 800) were collected throughout 3 protected areas located in the north (Ankarafantsika (AF) under ferruginous soil, n = 257), mid (Ambohitantely (AT) under ferrallitic soils, n= 278,) and the South-east (Ivohiboro (IV) under ferrallitic soils, n= 265) of Madagascar across 5 depth layers: 0-10 cm, 10-20 cm, 20-30 cm, 50-60 cm and 80-90 cm and considering 3 land use types: natural forest (Dry in AF, altitude humid for IV and AT), shrubland and grassland. Soil samples were dried and ground at 0.2 mm and analyzed by elemental analyzer-IRMS to get $\delta^{13}C$ and $\delta^{15}N$ values. Field-spec analyzer and PerkinElmer FT-IR Spectrometer Frontier were also used for the acquisition of NIR spectra (NIRS) and MIR spectra (MIRS), respectively. The isotopic modelling was achieved with locally weighted partial least squares regression (LW-PLSR) on MIRS and NIRS spectra separately. For both spectral ranges, the same samples were used for calibration (n = 600, selected for spectral representativeness) and for validation (n = 200). The prediction accuracy of the models was evaluated on the validation subset using the coefficient of determination ($R^2$) and the ratio of performance to deviation (RPD). The higher $R^2$ (>0.8) and RPD were (>2), the more accurate prediction model was.

Model based on MIRS yielded excellent prediction for $\delta^{13}C$ ($R^2$ of 0.80 and RPD of 2.22) compared to the NIRS ($R^2$ of 0.40 and RPD of 1.21). For $\delta^{15}N$ the NIRS ($R^2$ of 0.55 and RPD of 1.48 in validation) outperformed MIRS ($R^2$ of 0.42 and RPD of 1.41 in validation)) with poor prediction for both spectral ranges.
The better $\delta^{13}C$ performance of MIRS reflects its sensitivity to specific molecular vibrations associated with carbon functional groups, while the relatively higher $\delta^{15}N$ prediction from NIRS may result from weak N–H and amide overtones that correlate indirectly with nitrogen content.

These findings highlight MIR as a promising, cost-effective alternative to traditional isotopic analysis for monitoring carbon dynamics in Madagascar.

## ABSTRACT

Rapid detection of nitrogen in maize leaves is crucial for predicting precisely fertilizer requirements and ensuring efficiency and sustainability of production. In this research, near infrared spectroscopy had been examined for its potential for the diagnosis of the critical and insufficient levels of nitrogen element through dried maize leaf. Sixty-one samples of Dong-dan1331 cultivar were collected with whole plant at the 3- to 4-leaf stage and with the entire first mature leaf below the whorl before tasseling, respectively, from the pot experiment. The samples were dried in a 70°C forced air drying oven and finely ground, sieved through 0.5 mm sieve prior to chemical analysis and NIR scanning. Nitrogen in dried ground samples was determined by the vario EL III elemental analyzer (Elementar Analysensysteme GmbH, Germany). NIR spectra were measured by a MPA Multi Purpose FT-NIR Analyzer (Bruker Optics, Germany) in the reflectance mode. The scanning was performed by a OPUS program. Spectral data were exported into the Unscrambler software v.6.1 (Camo AS Trondheim, Norway) using the JDX formatted files for calibration development. Partial least squares regression (PLS) was used to establish the relationship between the spectra and the nitrogen nutrient content in maize leaves. Spectral pretreatment methods, such as conversion to absorbance, multiplicative scatter correction (MSC), mean normalization, moving average smoothing (with three adjacent spectral datapoints), Savitzky-Golay smoothing (with 7 averaging datapoints and a polynomial order of two), Norris first derivative (with a segment of 5 datapoints and a gap of 4 datapoints), Savitzky-Golay first derivative (with the convolution interval of 5 datapoints and a polynomial degree of 2), Savitzky-Golay second derivative (with the convolution interval of 13 datapoints and a polynomial degree of 2), and, or, a combination thereof, were used through the Unscrambler 6.01 software before calibration. PLS calibrations were developed with a full cross validation (leave-one-out validation) procedure. The parameters used to evaluate the quality of the calibrations were the coefficient of determination for calibration (Rc2) and for validation (Rv2), the root mean square error of cross validation (RMSECV), the root mean square error of calibration (RMSEC) (Esbensen et al., 1994), ratio of performance deviation (RPD) (Williams and Sobering, 1993; Chang et al. 2001) and the ratio error range, RER(Williams and Sobering, 1996). No sample outlier was excluded when making these calibrations.

The near-infrared spectroscopy combined with partial least squares (NIRS-PLS) model developed in this study not only demonstrates the feasibility of quantitative nitrogen analysis in corn, but also reveals the profound impact of spectral preprocessing on model performance through detailed parameter comparisons. Furthermore, it highlights the similarities and differences in model performance across samples from different growth stages. High coefficients of determination (R2>0.92) for seedling and tasseling samples were observed between the nitrogen contents determined by the elemental analyzer and those estimated by the FT-NIR Analyzer.All models achieved RPD values significantly above 3.0, strongly demonstrating their high accuracy and stability in samples. All models in this study demonstrated RER values above 20, with the highest reaching 31.33, further confirming reliable predictions across the entire nitrogen content range of test samples. In summary, the models developed in this study achieved meeting the needs for rapid and non-invasive diagnosis of maize nitrogen nutrition status.These results confirm that NIRS enables rapid and accurate quantitative analysis of nitrogen content in corn leaves. The optimal pretreatment method for seedling leaves was "mean normalization", which demonstrated the best performance with 6 factors (RMSECV=0.6816, RPD=5.64, RER=31.33). For the tasseling stage, the optimal pretreatment method was Savitsky-Gore first-order derivative, achieving the best results with 2 factors (RMSECV=0.8172, RPD=8.23, RER=28.02). The study reveals that the dominant factors influencing near-infrared spectroscopy vary significantly across different plant growth stages. Spectral data from whole-plant seedling samples demonstrated greater complexity. In contrast, leaf samples collected during the tasseling stage exhibited a more stable chemical composition, resulting in clearer and more distinct spectral characteristics of nitrogen content.

The study highlights the necessity of developing specific calibration models for different growth stages. Results demonstrated that by optimizing spectral preprocessing methods, near-infrared spectroscopy (NIRS) based on partial least squares regression can achieve high-precision and reliable quantitative analysis of nitrogen content in corn leaves. This provides an effective approach for rapid diagnosis of nitrogen nutrients and the foundation for subsequent nitrogen fertilizer recommendation.

**ABSTRACT**

The evaluation of soil properties is labour-intensive and time-consuming. The cost of laboratory analyses thus limits the spatial resolution of sampling. Therefore, in situ measurement of soil properties such as soil organic carbon (SOC) is urgently needed. Visible and near-infrared (Vis-NIR) spectroscopy is considered a feasible alternative for field measurements. The integration of Vis-NIR spectrometers and a penetrometer to obtain measurements of soil spectra in subsoils can greatly enhance the data acquisition rate and enable higher resolution sampling. In this study, a Vis-NIR penetrometer system was used to acquire soil spectra in the field conditions. The system utilised two low-cost spectrometers which cover 350-2500 nm. The penetrometer sampled soil spectra at 2-cm intervals, and spectra from five consecutive depths were averaged to represent a 10-cm interval, corresponding to a 10-cm core sample as ground truth data. The penetrometer is attached to hydraulic sampler enabling exploration up to 1 m depth. Soil spectra were acquired under field conditions at 18 locations in New South Wales, Australia. The spectra were calibrated with 130 soil samples collected in the field. Ten-fold cross-validation using a Cubist regression tree model yielded an R2 of 0.74 and a root mean squared error of 0.21%, indicating that the penetrometer can reliably predict SOC under field conditions. This penetrometer system enables acquisition of soil spectra to depths of up to 100 cm in under 5 minutes, facilitating rapid determination of SOC in the field.

# A comparative study of Random Forest and Neural Network with implementation of Boruta algorithm for predicting soil properties from Visible-Near Infrared spectra

**ABSTRACT**

Efficient monitoring of soil fertility and plant health is essential for sustainable agriculture. Visible and near-infrared (Vis-NIR) spectroscopy offers a rapid and non-destructive alternative to conventional soil analysis [Viscarra Rossel et al., 2006]. This study investigates the relationship between bare soil spectral reflectance curves and key soil properties: pH ($H_2O$ and KCl), content of organic matter, nitrogen (N), nitrate ($NO_3$), calcium (Ca), magnesium (Mg), and phosphorus (P). Specifically, by comparison the performance of a Random Forest model against an Artificial Neural Network. We collected a total of 30 soil samples from agricultural land (Moscow region, Vnukovsky district), represented by glossic Retisols. Diffuse reflectance spectra (325-1075 nm) were acquired using a FieldSpec HandHeld 2 spectroradiometer. Spectral preprocessing included Savitzky-Golay smoothing, Standard Normal Variate transformation, and first-derivative analysis. For automated feature selection to identify the most relevant wavelengths the Boruta algorithm was employed, which reduced the initial set of 741 wavelength to the range from 10 to 13 key wavelength without losing model accuracy. Comparative analysis revealed wavelength selection patterns across nutrients: organic matter content and related nutrients (N, NO3) showed stronger selection in visible regions (590-624 nm range), while mineral nutrients (Ca, Mg) and pH exhibited importance across broader spectral ranges (600-1050 nm). At the same time, some wavelengths (namely, 604, 605, 606, 607 nm) were same for several soil properties such as nitrogen, organic matter content and pH (both $H_2O$ and KCl), which demonstrates the general relationship between all important agronomic soil properties. The predictive performance for all properties was quite good (Pic. 1). The Random Forest model demonstrated superior performance for predicting nitrogen ($R^2 = 0.94$, RMSE = 0.01) and calcium ($R^2 = 0.92$, RMSE = 0.04) content. The ANN model achieved its highest accuracy for magnesium content ($R^2 = 0.97$, RMSE = 0.24). However, pH ($H_2O$) and phosphorus content showed lower predictability ($R^2 < 0.88$) with both methods, likely due to their complicated relationship with spectral features. This study demonstrates that Vis-NIR spectroscopy coupled with machine learning is a powerful tool for predicting several key soil properties.

## ABSTRACT

Visible near-infrared (vis-NIR) spectroscopy is a rapid, non-destructive, environmental-friendly, and cost-effective technique well suited for analyzing key soil properties. Over the years, numerous studies have used vis-NIR spectroscopy to generate huge amounts of soil spectral data, leading to the development of numerous soil spectral libraries (SSL) at global, national, and regional scales. These SSLs serve as large databases and can be used for both qualitative and quantitative soil analysis. With the advancements in machine learning (ML) and artificial intelligence, these can be leveraged to monitor soils at the local or farm scale. However, the transferability of such models can be challenging due to high heterogeneity and spatial and temporal variability in soil samples. Thus, the objective of this work was to investigate and improve the effectiveness of the Canadian Prairie Soil Spectral Library (CPSSL) to predict soil organic carbon (SOC) at three farms (local datasets) in the Canadian prairies. A global model for the Prairies was first created using 7924 samples from 2305 locations across the three Canadian prairie provinces, namely, Alberta, Saskatchewan, and Manitoba. This global model was then spiked with samples from the three local datasets (n = 130, 389 and 798, respectively). We used different spiking strategies to select the best spiking subset and spiking ratio. Different regression based and ML models were developed to predict SOC. Based on preliminary analysis, we observed that spiking the global model with 20% local samples significantly improved the local predictions (28% increase in coefficient of determination, and 17.4% decrease in root mean square error). Further analysis will focus on the spatial distribution of the samples to be used for spiking and the use of different combinations of feature selection algorithms and models to improve the predictability of the global model for local datasets. Another aspect of the study will investigate the use of subsets of the global dataset, based on soil type, management practices, and spectral similarities to improve the adaptability of global models for local predictions. Preliminary results will be presented and highlight the immense potential of a SSL for soil monitoring at local scales. This will help to fill soil data gaps and improve accessibility to critical soil information.

# Standardized Protocol for Soil Organic Matter Prediction using Vis-NIR Spectroscopy- A Meta-Analysis

**ABSTRACT**

The increased interest and adoption of precision agriculture techniques underscore the urgent need for spatially and temporally explicit soil data. Over the past few decades, spectroscopy has emerged as an effective tool for soil analysis. Numerous studies have employed visible near-infrared (vis-NIR) spectroscopy to quantify various soil properties. Amongst these, soil organic matter (SOM) has gained prominence in the research community due to the significant role it plays in agricultural systems, climate change, and its influence on a wide range of soil properties. However, there is no standard protocol for soil spectral analysis and hence the procedure used varies across studies, thus presenting obstacles in comparing and sharing the datasets and results. To address these challenges, the aim of this work is to develop an optimal standard protocol for soil spectral analysis in the vis-NIR range to predict SOM. We conducted a meta-analysis where 350 articles published from 1990 to 2024 were selected from three scientific search engines, namely Google Scholar, Web of Science and ProQuest. We collected protocol data from each of these studies and the extracted information encompassed different aspects such as laboratory or in-situ spectra collection, sampling approach, sample size, instrumentation, sample processing, spectra preprocessing, model training, and validation. This dataset provides a comprehensive overview of the wide array of methodological techniques applied across different procedural steps. Subgroup analysis was applied to observe the influence of the protocols on the performance of spectral models. Initial results highlight the major developments in the field of soil vis-NIR spectroscopy in terms of technology, accessibility, scalability, and adaptability. While it is broadly expanding, the adoption is not as uniform. Moreover, significant differences among the performance of different protocols were found. This can be attributed to the scale of the dataset, and differences in spectral acquisition and chemometrics analysis. Combining metadata with spectral data improved SOM predictability in some cases. Further analysis of this dataset will look at the best performing and most consistent protocol that can be used as a standard across different studies. This standard protocol can serve as a step towards enhancing the comparability and accessibility of soil vis-NIR spectral data.

# Carbon Assessment in Peat Soils Through Moisture-Corrected Vis–NIR Spectroscopy and Instrument Comparison

**Leonardo Pace*[1], Maria Knadel[2], Simone Priori[1], Peter Eniola[2], Fabio Castaldi[3], Triven Koganti[2]**

**ABSTRACT**

Peatlands are among the largest global carbon reservoirs; but the monitoring of such areas requires rapid and reliable methods for the estimation of soil properties. Visible and near-infrared spectroscopy (vis-NIRS) is widely used for Total Organic Carbon (TOC) assessment; however, the high-water content typical of peat strongly affects reflectance under field conditions, altering spectral features and reducing prediction accuracy. This study compares the performance of two different spectrometers, the ASD LabSpec (350–2550 nm) and the Si-Ware NeoSpectra Scanner (1350–2550 nm), for analyzing Danish peat soils under variable moisture conditions. The water absorption bands at 1400 and 1900 nm are the most affected by O–H overtones, these regions were therefore used to identify and isolate moisture-related spectral variability, which was subsequently removed from the full spectra before developing TOC prediction models with the full range of both instruments.

A total of 150 peat samples were collected and scanned in triplicate with both spectrometers. All samples were measured under dry conditions, and a subset of 60 was additionally rewetted to approximately 30%, 60%, and 90% gravimetric moisture content. To mitigate moisture interferences, External Parameter Orthogonalization (EPO) was applied as a multivariate correction technique aimed at removing water-induced spectral variance while preserving TOC-relevant information. The rewetted subset is being used to build the EPO model, which will then be applied to the entire dataset to improve model robustness and reduce moisture-driven discrepancies between the two instruments.

The main objectives of this work are: (i) to quantify the differences in moisture-related spectral response between LabSpec and NeoSpectra, (ii) to evaluate the effectiveness of EPO in reducing water-induced variability by comparing spectral distances and TOC model stability before and after correction, and (iii) to assess the improvement in TOC prediction accuracy after correction. Expected outcomes include identifying which instrument is less sensitive to moisture and therefore more suitable for field measurements and supporting the development of a practical workflow that enables the use of in-field spectra without requiring laboratory drying or sample preparation. This will contribute to more consistent VIS- NIRS based characterization of organic soils and more reliable carbon assessment in peatland monitoring.

**ABSTRACT**

Soils underpin food security, water quality, and the global carbon cycle, yet we lack fast, reliable tools to quantify the oxidative enzymes that govern how soil organic matter is stabilized or lost to the atmosphere. Measuring oxidative activities in soil is technically feasible using an *in vitro* soil enzyme assay that has been established for decades. However, the colorimetric method is time-consuming, labor-intensive, cost-inefficient and highly variable, making it impractical for large-scale or field-based monitoring. To address this challenge, we developed a spectroscopic method based on surface-enhanced Raman spectroscopy (SERS) and enabled fast and accurate monitoring of the two typical soil extracellular oxidative enzymes, horseradish peroxidase (HRP) and polyphenol oxidase (PPO). At the core of the new method, variations of SERS spectral patterns of L-DOPA are found to be a function of HRP or PPO concentrations through a partial least square (PLS) model. The model's performance remains satisfactory when applied to diverse soil samples collected in the Nashville Metropolitan area in TN, USA. In the future, we expect to generate spatially resolved real-time datasets that pinpoint potential soil health issues and empower AI-driven Microbial-Enzyme SOC modeling. Moreover, it holds potential to revolutionize real-time environmental monitoring of other environmentally relevant enzymes, such as hydrolases.

## ABSTRACT

Cocoa ranks as Papua New Guinea's (PNG) third most important agricultural export, providing livelihoods for ~2 million smallholder farmers, supporting Food Security. Recently, the condition and capacity of cocoa soils have deteriorated from inadequate nutrient management under intensified cocoa farming—with little soil monitoring and nutrient replenishment—due to resource-constraints. To rapidly and cost-effectively evaluate the condition of cocoa soils in PNG, this study presents the first comparison of visible and near-infrared (Vis-NIR) and mid-infrared (MIR) spectroscopy. We developed a spectral library by measuring 17 soil properties and spectral features from 507 soil samples collected at four smallholder cocoa farms across major cocoa production regions of PNG. Results showed that both Vis-NIR and MIR spectral features predicted over half of the soil properties with relatively high accuracy (Lin's concordance correlation coefficient ≥ 0.80), including: sand, clay, SOC, available N, available K (Vis-NIR only), exchangeable Ca, exchangeable Mg, Fe, Cu and Mn. MIR outperformed Vis-NIR in predicting soil texture and most chemical properties, while Vis-NIR provided slightly better predictions for certain nutrients—notably available K. The modelling results showed that between Cubist and partial-least-square regression (PLSR) models, Cubist models outperformed PLSR models for both Vis-NIR and MIR. Finally, MIR outperformed Vis-NIR in identifying soil minerals—such as kaolinite, gibbsite, halloysite, and calcite—using wavenumbers, making MIR the preferred spectroscopy method only when accurate mineral identification is required. These findings demonstrate Vis-NIR spectroscopy as the preferred and more practical method to effectively assess key soil properties for cocoa production—serving as a starting point for soil monitoring and nutrient management across cocoa farms in PNG—with broad applicability for soil monitoring and nutrient management in other resource constrained environments.

# Estimation of Soil Inorganic Carbon Based on Visible Near Infrared Reflectance Spectroscopy Absorption Depth

**Jiajing Gu[1], Yu Chen[1], Rong Zeng[1], Caixia Jiao[1], and Guanghui Zheng[1*]**

[1] *School of Geographic Sciences, Nanjing University ofInformation Science and Technology, Nanjing, China*

## ABSTRACT

Soil inorganic carbon (SIC) mainly occurs in the form of $CaCO_3$ and is essential in stabilizing the soil carbon pool and maintaining soil ecological functions. Previous studies have demonstrated that soil $CaCO_3$ content can be effectively estimated from visible-near infrared (Vis-NIR) reflectance spectroscopy using partial least squares regression and machine-learning approaches. However, these approaches are often methodologically complex and computationally intensive, which limits the applicability of simpler linear regression methods. Moreover, few studies have directly estimated calcium carbonate mass density from Vis-NIR reflectance spectroscopy.

A total of 43 soil profiles were collected from Cixi, Dongtai, Sheyang, and Tongzhou. Samples were obtained at 10 depth intervals within each profile. Figure 1 illustrates the procedures for soil property determination, spectral processing, and model development and evaluation.

The performance of different models for calibration and validation is presented in Table 1.

Results indicate the 2330-2360 nm spectral region exhibited the strongest correlation with $CaCO_3$ content; thus the maximum absorption depth within this range was defined as the absorption peak (AP). Models based on latent variables (LVs) combined with nonlinear regression achieved consistently high accuracy across both individual sites and the combined dataset (validation $R^2$ generally > 0.9). In contrast, AP-based linear models performed well at individual sites but showed substantial degradation when applied to the combined dataset (validation $R2 \approx 0.3$). Estimation accuracies for SICC*i* and SICD*i*cm were highly consistent. The strong correlation between SICC*i* and SICD*i*cm provides a physical basis for estimating SICD*i*cm using Vis-NIR reflectance spectroscopy (Figure 2).

In conclusion, the AP-based linear model represents a rapid and cost-effective alternative for localized SIC estimation. Direct estimation of SIC density at the one-centimeter soil layer using Vis-NIR reflectance spectroscopy was shown to be feasible.

**ABSTRACT**

Soil sample archives are increasingly valuable for research, particularly for testing spectroscopy with new sensor technologies and combinations. For this study, four distinct soil datasets were obtained from the Italian national archive of CREA, Florence, and were selected to maximize pedological and geographical diversity. The first dataset consists of Cambisols from Italy, while the second and third include Luvisols from Slovenia and Calcisols from Turkey, all collected from agricultural fields covering only a few hectares, representing small-scale, intensively managed areas. The fourth dataset was chosen to capture the broadest diversity, encompassing soils from Russian Chernozems to African Lixisols, representing 30 of the 32 WRB References Soil Groups (RSG). Clay content ranges from 0.1% in Arenosols to 96% in Nitisols, with sand content and organic carbon showing similarly wide variability. Each dataset contains 50–80 samples, including topsoil and subsoil layers, ensuring a representative range of soil conditions. The study compared an emerging low-cost NIR spectrometer (Polispec, TPhotonics, 900–1700 nm, direct contact) with a more established Vis–NIR spectrometer (ASD FieldSpec 3, 350–2500 nm). Polispec spectra were integrated with CIE Lab* color coordinates obtained with a NIX 2 Spectrophotometer and converted into Munsell spectra over 380–730 nm. To minimize differences due to instrument configuration and acquisition conditions when comparing spectral data from different SSL sources, the International Soil Standard (ISS) based on Lucky Bay white sand was applied. Instrumental comparisons revealed non-constant absorbance differences, with ASD readings on average about 10% higher than Polispec, highlighting the importance of standardized References and calibration. Key soil parameters—organic carbon, clay, and sand content—were modeled using Partial Least Squares (PLS) regression with Leave-One-Out (LOO) cross-validation. Validation with Polispec data showed moderate and variable performance: clay NRMSE 13–23%, $R^2$ 0.10–0.76; sand NRMSE 10–28%, $R^2$ 0.21–0.89; organic carbon NRMSE 13–23%, $R^2$ 0.12–0.76. Integration of VIS color spectra only marginally improved organic carbon predictions. Models based on ASD spectra showed superior predictive ability: clay NRMSE 6–19%, $R^2$ 0.20–0.93; sand NRMSE 10–17%, $R^2$ 0.14–0.86; organic carbon NRMSE 17–19%, $R^2$ 0.19–0.60. Despite limited variability in range, modest estimation performances were still observed. Restricting the spectral range to 1700–2500 nm caused substantial information loss, emphasizing the importance of broader spectral coverage for reliable soil property estimation.

# Vis–NIR Spectroscopy and Chemometrics for Soil Pollution Assessment: Challenges and Opportunities

**Erika Di Iorio[1*], Claudio Colombo[1*]**

[1] *University of Molise, Department of Agricultural, Environmental and Food Science, Campobasso (CB), Italy*

*colombo@unimol.it

**ABSTRACT**

Global soil contamination represents a critical environmental challenge, with heavy metals (HM) affecting 15–20% of agricultural and urban soils worldwide. These contaminants pose exceptional risks due to their persistence, bioaccumulation potential, and direct pathways into human food systems, creating cascading effects on public health and food security. The urgent need for rapid contamination assessment has driven significant advances in visible–near infrared (Vis–NIR) spectroscopy over the past two decades. This study aims to review the current advances in chemometric approaches using machine learning (ML) and recent methodological developments in Vis–NIR instrumentation. A conceptual framework is proposed to incorporate the variability of geographical settings, soil types, and pollution sources into predictive models. The ability to estimate HM contents with chemometric approaches, using both linear and non-linear models, relies on indirect correlations with other spectrally active soil components (such as clay minerals, organic matter, iron oxides, and primary minerals) that may co-vary with HM in the 400–2500 nm range. Key methodological advances involve robust spectral pre-processing (e.g. Savitzky–Golay filtering, orthogonal signal correction, standard normal variate) to reduce noise and improve absorbance spectra (−log(R)). Pre-processing is still a matter of debate, particularly regarding how contact conditions, distance, illumination geometry, may affect spectral responses, which is critical for field (on-the-go) applications where optical geometry is uncontrolled. For many proximal sensing tasks, it is not necessary to reconstruct the full spectrum (400–2500 nm); instead, short-range Vis–NIR (e.g. 400–1700 nm or 850–1700 nm) can be exploited, although this range remains comparatively underexplored. However, HM soil contamination is typically highly skewed and spatially heterogeneous, making global prediction models difficult to calibrate, strongly site-dependent, and challenging to transfer reliably to other regions. Spectroscopic approaches for soil metals, such as portable XRF, can help to perform better when combined with Vis–NIR spectroscopy, to reduce uncertainty of the models, and the heterogeneity of the sampling. To mitigate this, partitioning strategies divide large, heterogeneous survey areas into more homogeneous sub-areas, with optimal partitions is a possible approach. Ordinary cokriging can further improve Vis–NIR prediction models (300–2500 nm) by using variables such as soil organic matter (SOM), Fe and clay contents as covariates, in combination with non-linear ML methods (RF, SVM, ANN) that often outperform classical regression approaches (MLR, PCR, PLSR). In any case, the observed relationships tend to be highly site-specific and must be transferred to new soils or regions carefully when environmental and geographic conditions differ.

# Sample Transfer Learning for Improving Field-Scale Soil Organic Matter Inversion via UAV Hyperspectral Remote Sensing

**Xian-Li Xie[1,2*], Ruo-Tong Peng[3], Nuo-Xi Qiu[1,2] and An-Bo Li[3]**

*[1]State Key Laboratory of Soil and Sustainable Agriculture, Institute of Soil Science, Chinese Academy of Sciences, Nanjing 211135, China*

*[2]University of Chinese Academy of Sciences, Beijing 100049, China*

*[3]School of Geography, Nanjing Normal University, Nanjing 210023, China*

*E-mail: xlxie@issas.ac.cn

**ABSTRACT**

Field-scale soil organic matter (SOM) inversion via UAV hyperspectral remote sensing suffers from low accuracy, primarily attributed to the challenges of intensive sampling and low SOM variability within individual plots. This study employs a sample transfer learning method to expand the calibration sample set for field-scale UAV hyperspectral inversion and improve the accuracy of farmland SOM retrieval, by extracting training samples from a large soil spectral library.

The UAV hyperspectral dataset of a red soil dryland in Jiangxi Province, southern China was designated as the target domain. At this plot, a total of 50 topsoil samples were collected, and hyperspectral data (450–950 nm) were acquired using a DJI M300 UAV equipped with a Cubert S185 hyperspectral imager. These samples were partitioned into training and test sets at a 7:3 ratio. The source domain was a soil spectral database collected from soil series surveys across multiple Chinese provinces, comprising over 5,600 genetic horizon samples from approximately 1,400 soil profiles. Spectral reflectance data (350–2500 nm) of these samples were measured with a Cary 5000 spectrophotometer.

A comprehensive similarity index was established based on landscape and spectral similarities between source domain samples and the target domain training set. Source domain samples with comprehensive similarity above the threshold and SOM content within the preset range were selected as the source domain transfer sample set. This set was then merged with the target domain training set to generate an expanded training dataset for SOM spectral inversion modeling. Given that the target red soils contain high levels of free iron oxides, which typically mask SOM signals in soil spectral reflectance, the iron removal spectral preprocessing method proposed by Qiu et al. (2025) was adopted, followed by the construction of a SOM hyperspectral inversion model using the random forest algorithm.

Results indicated that, compared with the accuracy of the inversion model built using only the target domain training set (test set: $R^2$=0.31, RMSE=1.27 g/kg), the model built on the expanded training set yielded significantly higher accuracy for field-scale SOM inversion via UAV hyperspectral remote sensing (test set: $R^2$=0.66, RMSE=0.86 g/kg).

**ABSTRACT**

Accurate characterization of soil organic matter (SOM) is crucial for assessing soil fertility and its role in the global carbon cycle. The functionality of SOM depends not only on its total content but also on its chemical structure and composition, with stable organic matter serving as the primary functional component. Current research predominantly focuses on the total amount of SOM, lacking systematic investigation into its functional attributes. Traditional chemical analysis methods often disrupt the native structure of organic matter during extraction and measurement, and they tend to emphasize total content assessment, making it difficult to systematically elucidate the intrinsic relationship between molecular composition and stability. Therefore, this study employed in situ, non-destructive attenuated total reflectance Fourier transform infrared attenuated reflectance spectroscopy (ATR-FTIR), combined with partial least squares regression (PLSR) and multivariate statistical methods, to simultaneously obtain information on the content and structure of organic matter. The molecular structural characteristics and stability-driving mechanisms of organic matter in four typical agricultural soils in China—black soil, Fluvo-aquic soil, paddy soil, and red soil—were systematically analyzed. By performing peak fitting to extract the relative areas of aromatic C=C stretching vibration peaks at 1425, 1511, 1515, and 1660 $cm^{-1}$, a stability index (PI) was constructed to characterize the chemical stability of organic matter. The results revealed a clear inconsistency between the content and stability of organic matter across different soils. For example, black soil exhibited the highest total organic matter content but a significantly lower PI compared to Fluvo-aquic soil, indicating a lower proportion of stable components. Comparisons among different soil types further demonstrated that PI can simultaneously reflect both the "quantity" and "quality" of organic matter, addressing the limitations of traditional methods in functional characterization. By integrating spectral structural information with systematic comparisons across multiple soil types, this study provides theoretical support and methodological foundations for constructing an integrated quantity–quality evaluation system for soil organic matter.

## ABSTRACT

Soil profiles are central to the study of pedogenesis, with their genetic horizons directly reflecting soil-forming processes. Spectral technology is widely used in soil analysis and investigation due to its advantages of speed and non-destructiveness. The ASD reflectance spectrometer can acquire continuous high-resolution spectra, capturing subtle features such as organic matter and minerals, providing reliable data support for the efficient and non-destructive identification of genetic horizons.

This study focuses on a laterite soil profile. Using an ASD spectrometer equipped with a contact probe, 40 hyperspectral samples were collected at 2.5 cm intervals along a 1-meter deep profile. After preprocessing through averaging and Savitzky–Golay smoothing, a dataset for genetic horizon identification was constructed. Principal Component Analysis (PCA) was employed for dimensionality reduction to extract key spectral features, reduce redundancy, and enhance the representativeness of classification information. The dataset was then divided into a training set (60%) and a test set (40%) using stratified sampling. SVM excels in soil spectral classification due to its advantages in handling small-sample, high-dimensional, and nonlinear data.

The spectral characteristics of this laterite profile indicate that in the visible range, spectral reflectance decreases with increasing organic matter content, while overall reflectance gradually increases from the surface to deeper layers. An absorption feature around 850 nm reflects the high iron content in the profile. The above characteristics align with the soil-forming pattern of strong weathering and enrichment of iron-aluminum oxides in laterite under high-temperature and high-rainfall conditions.

Principal Component Analysis of the soil profile revealed that PC1 (accounting for 90% of the information) exhibits significant variation along the depth gradient, shifting from positive to negative values with increasing depth. PC2 (accounting for 9% of the information) shows minimal variation, fluctuating around zero. The first two principal components reflect the changes in attributes of each genetic horizon with depth.

Model validation results show that under 100 random samplings, the average accuracy reached 0.869, with most sampling accuracies concentrated around 0.9. With the optimal parameter combination, the model validation accuracy achieved 1, demonstrating the effectiveness of point-based hyperspectral data combined with machine learning algorithms. This method provides an efficient and non-destructive field solution for soil profile identification and classification, significantly enhancing the efficiency and accuracy of soil surveys.

**ABSTRACT**

Recent studies have demonstrated that the SIC stock (SICs) in the top 0-2 m of soil is comparable to the SOC stock (SOCs). SIC mainly exists in the form of calcium carbonate ($CaCO_3$) and influences soil buffering capacity and the availability of various nutrient elements.

In recent years, spectroscopic techniques have shown potential in the detection and quantification of SIC, particularly $CaCO_3$. However, existing studies have primarily focused on surface soil or discrete point samples, which cannot accurately reflect the continuous variation of $CaCO_3$ content or density with depth and the SICs.

The profiles were collected from the coastal plain of Dongtai, Sheyang, Tongzhou, and Cixi. In each profile, strip samples and bulk density samples were collected at 10 depth intervals: 0-5, 5-10, 10-15, 15-20, 20-30, 30-40, 40-50, 50-60, 60-80, and 80-100 cm. The $CaCO_3$ content was determinated by gas volume method and SICDicm was calculated using equation (1). The subsequent process of spectral data determination, preprocessing, calibration, and validation is shown in Fig. 1.

$$SICD_{icm}=SIC_i\times BD_i\times A\times(1-C_i)\div 10 \quad (1)$$

where, the letter A represents one centimeter.

The descriptive statistics for properties of calibration and validation sets were shown in Table 1. A strong linear relationship was found between measured SIC and SICDicm (Fig. 2). Therefore, it can be inferred that soil reflectance spectra should also be able to estimate SICDicm based on this linear relationship.

Results indicate excellent PLSR models were established, which can estimate SIC and SICDicm (Table 2 and Table 3). The SICDicm_40pre values estimated using the PLSR model were converted to SICDi_10pre and SICspre. The scatterplot indicates that the estimated results for SICDicm were very close to the determined values.

We can conclude that the strong linear relationship between SIC and SICDicm is the mechanism of SICDicm estimation using spectroscopy. Using continuously collected reflectance spectra along the profile allows both the mapping of the vertical SIC distribution and the estimation of SICs for the soil profile.

# Effect of spectral range, spectral pre-processing, calibration method, and sample classification on soil property predictions using a country-scale soil spectral library for Hungary

**Ádám Csorba[1*], Yuri Andrei Gelsleichter[1], Gábor Várszegi[2], Tamás Szegi[1], Márta Fuchs[1], Réka Döbröntey[1] and Erika Michéli[1]**

## ABSTRACT

Spectroscopy, particularly when integrated with conventional laboratory analyses, offers a rapid, non-destructive, and cost-effective approach for assessing soil properties. However, the accuracy of spectroscopic predictions depends on multiple factors, including the spectral region, pre-processing techniques, calibration models, and the method of sample grouping. In this study, we evaluated the predictive performance of a national-scale soil spectral library for Hungary by systematically testing how these factors influence the accuracy of soil property predictions, to identify optimal modeling strategies for large-scale applications.

The soil spectral library used in this study was developed within the framework of the Agrotechnology National Laboratory project. It is based on archived soil samples originally collected in 1992 as part of the Hungarian Soil Information and Monitoring System. These samples represent genetic soil horizons from 1236 geoReferencesd monitoring sites across Hungary and had previously been analysed for key physical and chemical properties. The References parameters used in this study included organic carbon, bulk density, particle size fractions (clay, silt, sand), pH, calcium carbonate, exchangeable bases (Ca, Mg, K, Na), exchangeable acidity, soluble salts, electrical conductivity, cation exchange capacity, and base saturation.

Spectral measurements were performed using two complementary instruments: ASD LabSpec 4 Hi-Res spectrometer for the visible and near-infrared (VNIR), and a Bruker Alpha II FTIR spectrometer for the middle-infrared (MIR) range.

To evaluate the predictive performance of soil spectroscopy under different modeling configurations, three algorithms were employed: Partial Least Squares Regression, Random Forest, and Cubist. Spectral data were used in three configurations - VNIR, MIR, and combined VNIR-MIR - and subjected to a range of pre-processing techniques, including raw spectra, moving average smoothing, Savitzky–Golay filtering, and first derivative transformations. All possible combinations of spectral type, pre-processing method, and calibration model were tested systematically.

To investigate how sample grouping affects model performance, the dataset was segmented into several categories according to various classification schemes. These included groupings based on parent material, main soil type (Hungarian classification), WRB References soil groups, textural class, county, elevation class, land cover, and unsupervised k-means clustering, in addition to the full dataset (no segmentation).

This paper presents the outcomes of this comprehensive modeling framework, highlighting how different spectral configurations, pre-processing techniques, calibration methods, and sample segmentation strategies influence the accuracy of soil property predictions across a national-scale spectral library.

# Layer–Profile Integration for Numerical Soil Classification

**Wartini Ng [1*], Alex McBratney[1]**

[1] *School of Life and Environmental Sciences & Sydney Institute of Agriculture, Faculty of Science, The University of Sydney, New South Wales 2015, Australia*

**ABSTRACT**

Numerical soil classification offers a scalable and objective alternative to traditional horizon-based systems, which depend on expert interpretation and are often challenging to apply consistently across complex and heterogeneous landscapes. In Australia, where soils exhibit pronounced spatial and vertical variability, numerical classification enables reproducible mapping based on measured or modelled soil properties.

Building on previous work that defined soil profile classes through clustering of soil properties across depth intervals, this study proposes a new framework to explicitly link profile classes with their constituent layer classes at the pixel level. The classification is based on a suite of relevant soil properties—available water capacity, bulk density, cation exchange capacity (CEC), effective CEC, pH (in both water and calcium chloride), organic carbon content, and soil texture (sand, silt, and clay percentages). The approach captures the vertical structure of soils by associating each profile class with the sequence of layer classes occurring across five standard depth intervals (0–5, 5–15, 15–30, 30–60, and 60–100 cm). By integrating depth-specific layer class maps with the profile class map at 90 m resolution across Australia, the framework will produce a national-scale, pixel-level composition table describing layer sequences within each profile. This linkage provides a means to quantify internal variability within profile classes and enhance the interpretability of classification outcomes.

This proposed framework has the potential to strengthen numerical soil classification by addressing inconsistencies in vertical composition and improving the functional relevance of soil maps. It establishes a foundation for assessing classification reliability, detecting horizon transitions, and analysing spatial patterns in soil organisation across diverse Australian landscapes.

**ABSTRACT**

A digitized soil map, accompanied by an associated and harmonized database, is crucial to support land management policies at the national level. Currently, the 1:250,000 scale soil map of Italy is complete, but it appears as a heterogeneous mosaic. Harmonizing cartographic units that are disjointed across different administrative areas, along with the inclusion of new soil profiles to increase detail, constitutes a complex and time and labor-intensive task (Fig1). The objective of this study is to test a semi-automatic numerical classification process to correlate the Soil Typological Subunits (STS) of the Coastal Soil Region 60.7, located between Tuscany and Lazio. The References database includes 1200 soil profiles, organized into 187 STS, representing 19 different References Soil Groups (RSG) according to the WRB 2022 classification system.

The profile comparison integrates both horizon-level and site-level attributes, including continuous properties and categorical variables. The analysis was conducted in R using the aqp v.2.1 package (Algorithms for Quantitative Pedology). The workflow involved creating a SoilProfileCollection object, deriving the distance matrix, and using it as the basis for clustering.

The innovative aspect lies in the handling of ordinal data, allowing a quantitative treatment of qualitative variables (e.g., horizon names, drainage classes), and in the integration of RSG taxonomic distances. Preliminary results, evaluated with statistical indices such as cophenetic correlation, indicate that the DIANA (Divisive Analysis) clustering algorithm performs very well on datasets containing between a few dozen (≈50) and several hundred (≈500) profiles.

Finally, the positioning of soil profiles via nMDS plots (non-Metric Multidimensional Scaling), following the clustering, proved to be an objective method for: (i) the semi-automatic assignment of new profiles to existing STS, and (ii) assessing the proximity between STS along the border between Lazio and Tuscany. (iii) The fully automated reassignment of profiles to clusters, however, differs significantly from the results reported in the regional soil-type catalogues, more so when many variables are considered.

Fig1 *Diagram that illustrates soil correlation is a continuous process, not a single event.*

# Transformation of Aluminum Forms During Andosol Genesis in Japan

**Syuntaro Hiradate**[1*]

[1] *Faculty of Agriculture, Kyushu University, Fukuoka, Japan*

*E-mail: hiradate@agr.kyushu-u.ac.jp

**ABSTRACT**

Significant changes in the chemical forms of aluminum (Al) occur during the formation of Andosols. Based on data published in the literature, the author reviewed the changes in Al speciation during the pedogenesis of Andosols under warm and humid climates. In the parent material, volcanic ash, Al exists in tetrahedral form, and it initially undergoes a transformation to octahedral form in the early stages of weathering. At this stage, the octahedral Al forms amorphous materials, which later become constituents of poorly crystalline aluminosilicate minerals, primarily allophane and imogolite (collectively referred to as allophanic materials). The formation of allophanic materials would require ca. 1 k years or more. Andosols with high contents of allophanic materials correspond to Allophanic Andosols, whereas earlier-stage Andosols correspond to Vitric Andosols. Allophanic materials are metastable and cannot maintain their structure under strong acidification, as they dissolve. Consequently, under humid conditions, the disappearance of allophanic materials occurs in the strongly acidified surface horizon, and the octahedral Al in allophanic materials is converted into Al-humus complexes. Some dissolved Al becomes exchangeable Al, which strongly inhibits plant growth. At this stage, the soils correspond to Non-allophanic Andosols. In Japan, Andosols derived from volcanic ash erupted during the Holocene (ca. 12 k years ago to the present) generally correspond to Vitric or Allophanic Andosols, whereas those derived from older volcanic ash correspond to Non-allophanic Andosols. Even in Non-allophanic Andosols, the subsoil receives less acid from precipitation or plants, resulting in weaker acidification compared to the surface horizon; therefore, the content of allophanic materials is considered higher in the subsoils. This explains the actual morphological features of Andosol profiles well. With further weathering, Al would become a constituent of more crystalline and thermodynamically stable minerals such as gibbsite and halloysite, and the soils cease to be Andosols. Thus, focusing on Al provides a better understanding of the formation and profile morphology of Andosols under warm and humid climates.

**ABSTRACT**

Most soil classification systems developed before computers and computer supported decision methods became available. Activities based on earlier and current international and national systems resulted in huge amount of data. The diversity of different survey, laboratory and classification methods make difficult to produce harmonized, quantitative data and mapping frameworks.

Pedometric approaches (centroid methods, distance calculations) proved to be useful to asses pedodiversity. The paper will summarize and exemplify some of those efforts.

The second part of the presentation will discuss the possibility to apply new objective data sources, such as remote and proxy-sensing technologies to support the understanding of existing and unknown relationships. Examples of applications of conventional laboratory and spectral data-based evaluations of soil similarities and differences will be presented.

# Water-Microbe-Mediated Rhizosphere Microbial Communities Reshaping Agroecosystem Resilience

**Gary Y. Gan* and Li Wang**

*College of Life and Environmental Science, Zhejiang Provincial Key Lab for Water Environment and Marine Biological Resources Protection, Wenzhou University, Wenzhou 325035, China*

*gary.gan@wzu.edu.cn

**ABSTRACT**

The agricultural 'Green Revolution' has substantially mitigated global food scarcity; however, over-reliance on chemical inputs—including fertilizers and pesticides—has triggered severe soil degradation and widespread environmental pollution, which exacerbates agroecosystem vulnerability against the pressure of climate change. This study identifies water-microbe-mediated rhizosphere microbial communities (SynComs) as the core mechanism for reshaping agroecosystem resilience, with improving soil health as the pivotal entry point for the transition from conventional intensive farming to low-carbon green agriculture. We propose three quantitative breakthroughs for this transition: a 30% reduction in chemical fertilizer and pesticide use, a 20-50% increase in water- and nutrient-use efficiencies, and a 10-30% increase in water-to-carbon biotransformation in rainfed dryland ecosystems. As soil water-microbe-mediated rhizosphere microbial communities are the key factors for this transition, we construct a systemic framework, encompassing the design of climate-smart SynComs, exploration of biophysical pathways for water-to-carbon biotransformation, development of bio-based nitrogen fixation, and exploitation of water-sensed bio-enhancers, all oriented to the triple strategic goals of safeguarding food security, maintaining soil health, and cutting greenhouse gas emissions. Leveraging water-microbe-mediated rhizosphere microbial communities, we establish a pipeline for novel SynComs via high-throughput isolation of functional microorganisms, single-cell Raman-based sorting of active microbial strains, and precise assembly of functional microbiomes. Large-scale field trials under Zhejiang Province's agricultural science and technology program validate the efficacy of this water-microbe-mediated SynComs. The bio-enhancers increased rice yields by 16.6–17.8%, while nitrogen-fixing biofertilizers effectively enhance soil health. These findings reveal that water-microbe-mediated rhizosphere SynComs serve as the core ecological engine governing material and energy cycling in agroecosystems, and that soil microhabitat regulation constitutes an effective pathway for the sustainable transformation of global agriculture. Delivering pivotal scientific insights into the restoration of soil health, the governance of food security, and national dual-carbon strategic objectives, SynComs fortify the agroecosystem resilience amid the context of anthropogenically driven climate change and its cascading ecological impacts.

# Confronting Water Availability versus Water Accessibility in Plant–Soil Relations

**Ying Zhao**

*Ludong University*

**ABSTRACT**

Water availability has long been a key parameter in hydrology, agronomy, and plant physiology, but recent advances highlight the necessity of distinguishing it from water accessibility – the fraction of soil water that plants can actually extract for physiological functions. Water availability is traditionally quantified as the difference between field capacity and the permanent wilting point, yet this metric does not account for soil structure, root system architecture, and dynamic soil–plant interactions that influence how much water is actually accessible to vegetation. This report synthesizes recent findings on the physical and biological controls of water accessibility, explores its implications for ecohydrology and climate resilience, and discusses how next-generation models can better integrate accessibility to improve predictions of drought stress, ecosystem water use efficiency, and land–atmosphere feedbacks. Recognizing the role of water accessibility in plant–soil relations provides a more nuanced understanding of drought impacts, crop water use, and the hydrological cycle under a changing climate.

# Physically informed Bayesian mixing models reveal more realistic root water uptake profile

[4] *College of Resources and Environmental Engineering, Ludong University, Yantai, China*

*fuhan@iga.ac.cn

**ABSTRACT**

Root water uptake is critical for plant water relations and ecosystem functioning, yet accurately quantifying depth-specific root water uptake profiles remain challenging due to limited isotopic constraints and underdetermined mixing solutions. Here, we introduce CrisPy-Physical, an isotope-based Bayesian mixing model that integrates a physically based root water uptake process into a continuous nonparametric estimation framework. Virtual tests demonstrated that CrisPy-Physical substantially reduced errors and uncertainties of estimated root water uptake profiles by 90% and 60% than the previously developed CrisPy (with no physical constraints), respectively. Notably, CrisPy-Physical successfully reproduced hydraulic redistribution patterns, which CrisPy failed to capture. Field tests in a vegetated lysimeter showed that both CrisPy and CrisPy-Physical captured the drought-induced shift of root water uptake towards deeper soil layers and its subsequent reallocation to shallow layers after rainfall. However, CrisPy barely captures root water uptake below 1.5 m, contradicting physiological expectations supported by fine-root profiles and water potentials between leaf and soil. Overall, CrisPy-Physical not only offers a robust and physically consistent framework for inferring root water uptake profiles, but also advances our mechanistic understanding of plant water use strategies under various climate conditions.

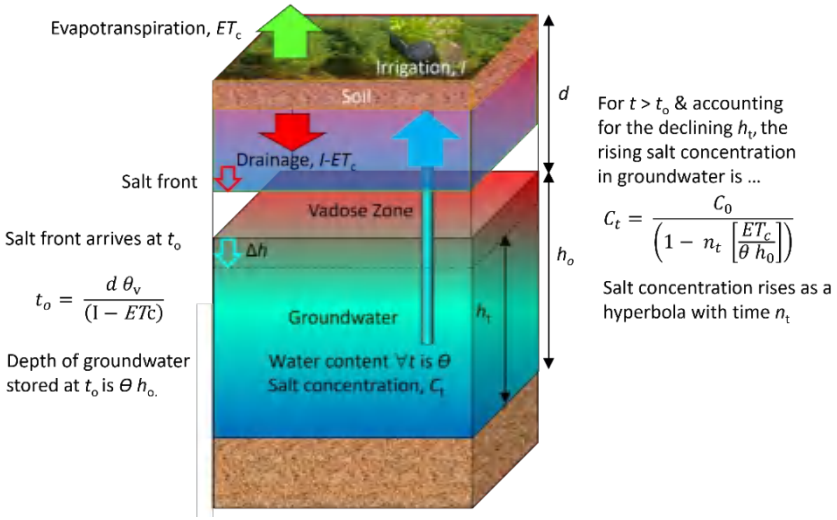
# Soil-Water and Groundwater: Connections at the Food-Water-Energy Nexus

**Brent Clothier**[1*]



[1]*Bioeconomy Science Institute, Plant & Food Group, Palmerston North, New Zealand*

*brent.clothier@plantandfood.co.nz

## ABSTRACT

Globally there are critical opportunities and profound challenges at the food-water-energy nexus. Crucial to the nexus is the role of soil-water and groundwater. Soil-water is needed to produce food. Groundwaters provide 99% of the world's useable freshwater supplies. Agriculture consumes 70% of the world's freshwater. From the 2010 baseline there is projected to be 56% gap in food production by 2050. Irrigation is required for much of the world's food production, as 40% of the food grown globally uses irrigation. Yet some 10% of today's irrigation water is "stolen" from tomorrow, as it relies on today's use of non-renewable groundwater to produce food. It has recently been suggested that with "business-as-usual", we will reach "peak groundwater" around 2050.

Groundwater-protection measures are needed for agricultural production of food, fibre, and fuel in the deserts of the United Arab Emirates (UAE). Our work in the UAE① focussed on groundwater protection under the production of the halophyte *Salicornia* growing in a sandy soil using irrigation with the reject brine from a desalination unit. Energy is used to desalinate the brackish groundwater in desert realms. The freshened water can be used to irrigate high-value crops with low salinity tolerance such as vegetables or dates. With irrigation of halophyte using the reject brine from desalination units, a leaching-fraction is needed to despatch the residual salts out of the rootzone back to groundwater. Heuristic modelling predicts a hyperbolic rise in groundwater salinity.

Solutions to extend groundwater life could involve using zero-liquid-discharge desalination, or the conjunctive use of alternative waters, either directly as an irrigation, or indirectly via blending or managed aquifer recharge. There are environmental opportunities and challenges at the nexus. Sustainable solutions will rely on innovations and stakeholder discussions to assess benefits, synergies, trade-offs, and the impacts of various options.

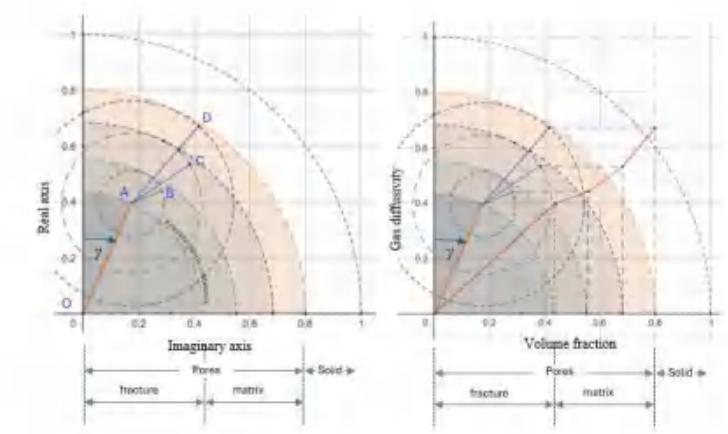
## ABSTRACT



Knowledge of gas diffusivity ($D_p/D_o$, where $D_p$ and $D_o$ are gas diffusion coefficients in soil and in free air, respectively) and its relationship to moisture is as essential prerequisite for quantifying soil–atmosphere interactions in both natural and engineered porous systems. Traditional power-law expressions for predicting $D_p/D_o$ largely rely on empirical parameters that obscure the directional complexity of pore networks, particularly under variable saturation and structural anisotropy.

In this study, we present a unified complex-plane framework that represents gas diffusivity as a vector-derived quantity to represent variably saturated media and fracture-matrix systems. The framework introduces a dual impedance concept, where air-phase availability defines the impedance magnitude, and directional changes in diffusive flow appear as a phase shift on an Argand plane. This approach captures the evolving geometry and directionality of gas transport as soils transition from dry to wet states or from fracture- to matrix-dominated domains.

Using new and published $D_p/D_o$ data, we demonstrate how the effective impedance angle evolves with changing water content and structural orientation. For variably saturated media, increasing moisture rotates the principal diffusion axis, reflecting a transition from freely connected air pathways to moisture-constrained pore connectivity. For fractured media, the framework generalizes single and multiple fractures of varying orientations by mapping fracture porosity and alignment as angular components in the complex plane. Fractures impose a baseline anisotropy, while matrix pores contribute an omnidirectional component as water drainage progresses, producing distinct diffusivity trajectories in the complex domain.

Application to fractured limestone revealed a transition from a fracture-controlled regime (mean impedance angle ≈58°), through an interactive fracture–matrix regime (≈85°), to a matrix-controlled regime (≈65°), consistent with evolving hydraulic connectivity. This complex-plane representation provides a mechanistically meaningful approach to describe moisture-induced rotation of the principal diffusion axis in variably saturated soils, enabling improved characterization of soil aeration, $CO_2$ flux, vapor transport, while capturing preferential gas flow and fracture–matrix exchange dynamics in fractured media.

The accompanying figure illustrates the complex-plane representation of fracture–matrix duality and the corresponding trajectories of soil-gas diffusivity across the two domains.

## ABSTRACT

Gravity potential difference irrigation (GPDI) systems maintain a stable water level within the irrigator, leveraging the combined effects of soil matrix potential and gravity potential to continuously supply water to the crop root zone based on plant water demand. This study investigated the soil water infiltration characteristics under GPDI and the factors affecting them. Nine scenarios of irrigator opening adjustments were designed: experimental irrigator openings were set at 6 cm, 2 cm, and 1 cm, while the filling thickness of the capillary soil layer within the irrigator were set at 9 cm, 6 cm, and 3 cm, respectively. Wetting patterns were analyzed using image processing. The discharge of GPDI and the moisture distribution within the wetting patterns were also analyzed. Furthermore, based on the hydraulic potential difference-driven outflow mechanism, a soil water movement model for GPDI was developed using HYDRUS-2D software. The accuracy of the model was validated with measured data from indoor experiments. Simulation results under different scenarios indicated that moisture primarily concentrated near the irrigator under GPDI. Adjusting the irrigator opening and the thickness of the capillary soil layer significantly affected the irrigator's discharge rate, moisture distribution, and wetting morphology. Specifically, larger irrigator openings and thinner capillary soil layers resulted in larger wetting areas and faster wetting front advancement, with higher soil saturation near the irrigator outlet. However, in scenarios with a 1 cm irrigator opening and a 9 cm capillary soil layer, the soil was less likely to reach saturation. The burial depth of the irrigator significantly influenced the position of the wetted body and the time for the wetting front to reach the upper and lower boundaries. Yet, before the wetting front reached the boundaries, its impact on GPDI outflow and wetting front advancement rate was not significant. This study provides a scientific References for the design optimization, management, and further promotion of GPDI technology

# Impact of Biosolids on Plant Available Water and Beyond

**Markus Flury**[1]

*1Department of Crop & Soil Sciences, Washington State University,*

*Puyallup, WA 98371, and Pullman, WA 9916, USA*

*flury@wsu.edu

**ABSTRACT**

The use of biosolids in agricultural practices is prevalent to enhance soil fertility and water retention. Biosolids are rich in nutrients and organic matter; thus, land-application of biosolids contributes to circular economy principles. However, biosolids also contain contaminants, such as microplastics, which can lead to pollution of soils and deterioration of soil functions. Long-term biosolids application significantly improved soil chemical and physical properties, with organic matter increasing by up to 71%, bulk density decreasing by 22%, and field capacity increasing by 24%; however, biosolids application also led to a decrease of pH from 5.5 to 4.8. Enhanced pore connectivity revealed by X-ray computed tomography provides microscale explanation for improved water retention. While biosolids applications increased soil organic matter and microplastic concentrations in the soil, correlation analysis revealed a negative relationship between organic carbon and extractable microplastics when controlling for biosolids application dose. In addition, soil physical parameters were more strongly correlated with organic matter than with microplastics concentrations, suggesting that the impacts of organic matter dominates over microplastics. Our findings demonstrate that benefits of biosolids outweigh quantifiable short to medium-term risks from associated microplastics, though long-term monitoring remains essential.

# Root zone in the Earth system

**Hongkai Gao** [1]

[1] *School of Geographic Sciences, East China Normal University, Shanghai 200241, China*

hkgao@geo.ecnu.edu.cn

**ABSTRACT**

The root zone is a vital part of the Earth system and a key element in hydrology, ecology, agronomy, and land surface processes. However, its definition varies across disciplines, creating barriers to interdisciplinary understanding. Moreover, characterizing the root zone is challenging due to a lack of consensus on definition, estimation methods, and their merits and limitations. This paper provides a holistic definition of the root zone from a hydrology perspective, including its moisture storage, deficit, and storage capacity. We demonstrate that the root zone plays a critical role in the biosphere, pedosphere, rhizosphere, lithosphere, atmosphere, and cryosphere of the Earth system. We underscore the limitations of the traditional reductionist approach in modeling this complex and dynamic zone and advocate for a shift towards a holistic, ecosystem-centered approach. We argue that a holistic approach offers a more systematic, simple, dynamic, scalable, and observable way to describing and predicting the role of the root zone in Earth system science.

# Predawn Leaf Water Potential of Grapevines Is Not Necessarily a Good Proxy for Soil Moisture

**Yingxue Yu**[1*]

[1] *Department of Ecosystem Science and Management, The Pennsylvania State University, University Park, PA16802*

* yqy5525@psu.edu

**ABSTRACT**

In plant water relations research, predawn leaf water potential (Ψpd) is often used as a proxy for soil water potential (Ψsoil), without testing the underlying assumptions that nighttime transpiration is negligible and that enough time has passed for a hydrostatic equilibrium to be established. The goal of this research was to test the assumption Ψpd = Ψsoil for field-grown grapevines. A field trial was conducted with 30 different cultivars of wine grapes grown in a single vineyard in arid southeastern Washington, USA, for two years. The Ψpd and the volumetric soil water content (θv) under each sampled plant were measured multiple times during several dry-down cycles. The results show that in wet soil (Ψsoil > −0.14 MPa), Ψpd was significantly lower than Ψsoil for all 30 cultivars. Under dry soil conditions (Ψsoil < −0.14 MPa) Ψpd lined up better with Ψsoil. These results suggest that for wet soils Ψpd of grapevines cannot be used as a proxy for Ψsoil, while the Ψpd = Ψsoil assumption may hold for dry soils.

# Water Balance and Plant Available Soil Water: Linking Soil Physics and Hydrology

**Allen G. Hunt* and Behzad Ghanbarian**

[1] *Physics Dept., Wright State University, Dayton, USA*

[2] *Earth and Environmental Sciences Dept., University of Texas Arlington, Arlington, USA*

*allen.hunt@wright.edu

**ABSTRACT**

The water balance, referred to by Robert Horton as the "central problem of hydrology," and plant available soil water are closely, though imprecisely, linked. Predicting the water balance requires prediction, as a function of climate variables (precipitation and potential evapotranspiration), of the fraction of the precipitation used by vegetation. Contrastingly, plant available soil water is considered to be the water "held in soil that is accessible for plant roots to absorb after excess water drains," bounded by the permanent wilting point." Such a description is not clearly enough defined to enable scientific tests of prediction by measurement and implies furthermore a temporal distinction (at some times water is draining from the soil, while at others, water is being used by the plants) which clearly does not exist. However, the amount of water actually used by plants can be measured and predicted. Of late, the hydrology community has been gravitating to the perspective that it is not primarily the physical properties of the soil that control the behavior of the plants, but the adaptation of vegetation and the living soil to the climate system that control soil development, plant growth, and the physical properties of the soil.

In our perspective, the plant use of precipitation, i.e., actual evapotranspiration (not precisely water held in the soil) and the water that is left over to form soil, i.e., run-off, can only be understood if one establishes first what the dependence of plant growth is on evapotranspiration, and of soil depth on run-off. Only then, can one find an optimal partitioning of P into Q and ET which maximizes plant and microbial productivity. Thus, the point of view that plants determine the water content of the soil, rather than that the water content of the soil controls plant growth, can form the basis of a successful theory of the water balance, vegetation growth, and productivity, even if it is not the entire picture. The benefits of this change in perspective are large: 1) Predictive capability of streamflow response to climate change, including climate and basin size dependence of elasticity and storage fluctuations, 2) associated predictive treatments of moisture recycling and scale dependence of ET, 3) Predictive capability of the variability of net primary productivity across biomes and climates, 4) Predictive capability of tree species richness, 5) Verified predictions of continental scale ET, 6) Understanding the current latitudinal dependence of vegetational optimality temperatures and the Phanerozoic global temperature record.

# A Process-Based Proxy for the Water Availability to Plants

**Quirijn de Jong van Lier**[1*]

[1] *Universidade de São Paulo (Center for Nuclear Energy in Agriculture, Piracicaba-SP, Brazil)*

*qdjvlier@usp.br

**ABSTRACT**

Total plant available water (TAW) is traditionally defined as the difference between field capacity (FC) and wilting point (WP). The portion of TAW between FC and the limiting point (LP) supports potential transpiration without drought stress and is referred to as readily available water (RAW). However, using FC as the upper limit of both TAW and RAW is questionable (De Jong Van Lier, 2017; Logsdon, 2019). Plants can continue transpiring at rates above FC, meaning that water beyond the traditional TAW range is effectively available. This additional water depends on soil hydraulic properties (SHP) and rainfall and crop characteristics, so an equivalent water content defining the upper limit of TAW and RAW must reflect both SHP, climate and crop. This revised concept will be discussed.

The lower TAW limit (WP) is commonly assigned to a matric potential of hWP = 1,500 kPa. Because most soils show a very small derivative dθ/dh at such high suction, WP is relatively insensitive to the exact value of hWP. By contrast, there is no widely accepted matric potential for the lower limit of RAW (LP). In the range where LP is typically located, dθ/dh is larger, making LP more sensitive to definition. Empirical approaches define LP based on FC, WP, atmospheric demand, and crop sensitivity (Raes et al., 2009) or as matric potential thresholds tied to crop type and evaporative demand (Feddes et al., 1978). These proxies, however, do not account for unsaturated hydraulic conductivity, a key determinant in process-based root water uptake (RWU) models (De Jong Van Lier et al., 2013). A new framework for LP and WP using process-based RWU models and the matric flux potential (the integral of hydraulic conductivity) will be presented.

Flux-based TAW and RAW derived from these dynamic limits will be compared with traditional estimates for a diverse soil set, and their relationships with crop behavior and soil water balance components will be discussed.

# Defining, monitoring, and utilizing plant available water information as a public good

**Tyson E. Ochsner and Erik S. Krueger**

*Department of Plant and Soil Sciences, Oklahoma State University, Stillwater, Oklahoma, USA*

tyson.ochsner@okstate.edu

**ABSTRACT**

Plant available water (PAW) is a misunderstood and underappreciated global water resource, and there is tremendous potential for improved PAW monitoring to provide diverse societal benefits. Unlocking that potential requires, first, a correction of the widely accepted but inaccurate way in which the upper limit of PAW, i.e. field capacity, has been estimated for almost a century. Estimating field capacity as the volumetric water content of the soil at a matric potential of -33 kPa consistently underestimates field capacity by ~20%, leading to significant underestimates of PAW. Better field capacity estimates are possible by interpreting data from in situ soil moisture sensors or by using matric potential thresholds of -10 kPa or even -7.5 kPa. Using a matric potential of −33 kPa as a threshold to represent field capacity is not scientifically justified and should be discontinued. Adopting better field capacity estimates opens the door to developing beneficial PAW monitoring systems at socially relevant scales. One such system is the Oklahoma Mesonet, which includes one of the world's longest running soil moisture monitoring networks. This system provides automated daily statewide PAW observations for three depths, which are routinely used by the public. Those data are also converted to fraction of available water capacity (FAW) values, such that FAW = 1 corresponds to field capacity and FAW = 0 corresponds to permanent wilting point. These FAW values can be used for the public good through improved wildfire danger forecasting, better drought monitoring, more effective targeting of drought relief payments, and more. As researchers and stakeholders continue to unlock these benefits, we may move closer to a day when knowing current PAW levels will be as commonplace as knowing today's air temperature or rainfall amount.

**ABSTRACT**

Pre-consolidation stress is a measure of mechanical stability on the bulk soil scale while aggregate stability and penetration resistance measurements can be used to assess soil strength at the micro/root scale. Starting from initial soil deposition soil stability is expected to develop over time by processes like consolidation, shrinking-swelling, root reinforcement or exudation of mucilage by roots. We studied the development of soil stability over a cropping period from 2019-2024 in Bad Lauchstädt (Germany) where excavated plots were refilled with homogenized loam and sand and planted with two contrasting maize (*Zea mays*, L.) genotypes. On the field scale loam plots showed a distinct increase of pre-consolidation stress for the first three years while sand plots did not display any temporal pattern (Rosskopf et al. 2022a). In a second laboratory study employing the same homogenised substrates we investigated the combined effect of mucilage concentration and soil water content on penetration resistance PR (Rosskopf et al. 2022b). A stainless-steel cone resembling the maize root geometry was mounted on a high-precision material testing device and pushed through the remoulded soil samples to simulate root growth. Loam and sand were mixed with chia (*Salvia hispanica,* L.) seed mucilage at various concentrations and samples were adjusted to a range of water contents. Higher mucilage concentrations significantly lowered PR in the driest loam, thus reducing the energy cost of plant root growth whereas in moister conditions it had the opposite effect. In a third study we investigated the direct effect of root growth on local soil deformation in the rhizosphere using X-ray mCT measurements and digital image correlation (Rosskopf et al. 2025). We could show that the extent of the deformation zone depended on soil texture and genotype. Our results provide valuable information on soil stabilisation processes during initial soil formation and highlight the complex interaction of physical and biological stabilisation mechanisms on various scales.

# Rhizosphere Hydraulic Regulation Across Soil Textures: Evidence for Texture-Dependent Mucilage Function

**Mohsen Zare[1*], Bahareh Hosseini[1], Ruth Adamczewski[1], Samantha Spinoso Sosa[1]**

[1] *Professorship for Soil Biophysics and Environmental Systems, Technical University of Munich, Germany*

*Mohsen.zare@tum.de

**ABSTRACT**

Plants actively modify the physical and chemical properties of the rhizosphere to overcome water and nutrient limitations. Root mucilage is increasingly recognized as a central regulator of rhizosphere hydraulic properties, yet quantitative evidence for how its function varies across soil textures and moisture regimes remains limited.

We combined a series of complementary experiments to address this gap. First, we used a simplified rhizosphere model to examine how varying concentrations of mucilage extracted from maize seedlings alter soil water retention, unsaturated hydraulic conductivity, and solute diffusion in sand, sandy loam, and loam across different moisture levels. In parallel, we conducted a $^{14}C$ pulse-labelling experiment together with neutron radiography to quantify how plants regulate belowground carbon allocation, specifically root exudation, under contrasting soil texture and moisture conditions, and how this carbon investment feeds back on rhizosphere hydraulic properties.

The rhizosphere model revealed pronounced texture-dependent mucilage effects. Coarse-textured soils required higher mucilage concentrations to increase water-holding capacity, whereas even low mucilage levels enhanced retention in finer soils. In sandy soils, mucilage reduced Ca diffusion by increasing liquid-phase viscosity across moisture levels. In contrast, in fine-textured soils, mucilage prevented the sharp decline in diffusion during drying, indicating improved liquid connectivity.

Neutron radiography of 6-week-old maize plants showed consistently wetter rhizosphere zones compared to bulk soil, with the strongest moisture gradients in sandy soils, evidence of enhanced mucilage-mediated hydration where hydraulic continuity is naturally low. The $^{14}C$ pulse-labelling experiment further demonstrated that carbon allocation to the rhizosphere is regulated by soil physical conditions: seminal and lateral roots in sand exhibited higher $^{14}C$ activity than in loam, particularly under dry conditions, and crown roots exuded the most $^{14}C$-labelled carbon in sand–dry soils. Root growth patterns confirmed sustained investment into seminal and lateral roots in sandy soils.

Together, these findings provide converging empirical evidence, from rhizosphere models, neutron imaging, and carbon tracing, that plants exude more, and hydraulically more effective, mucilage in sandy soils. This texture-dependent adjustment enhances water-holding capacity and stabilizes hydraulic continuity where roots would otherwise experience rapid drying. Our results reveal a mechanistic link between soil texture, carbon allocation to exudation, and rhizosphere hydraulic regulation, offering new insights into plant drought responses and informing soil- and crop-specific strategies to improve root-zone water availability.

# Estimating Soil Water Matric Potential from Penetration Resistance Measurements

**Chao Wang[1*], Yili Lu[1], Tusheng Ren[1], Robert Horton[2]**

**ABSTRACT**

Accurate quantification of soil water matric potential is critical for modeling soil water dynamics and optimizing irrigation management. Direct measurement methods are often limited by narrow operational ranges (e.g., 0 to -85 kPa for tensiometers) and high maintenance requirements. While commercial automated sensors offer improved accuracy and convenience, their cost remains prohibitive for field applications. Here we propose a rapid, cost-effective approach for estimating soil water matric potential (expressed as pF) from penetration resistance (PR) measurements. We conducted controlled laboratory experiments using repacked soil columns with nine soil textures ranging from quartz sand to clay. Tensiomark sensors and a cone penetrometer were used to simultaneously measure pF and PR during soil drying cycles across varying bulk densities (1.1-1.6 g cm-3). Results demonstrated that: (1) both instruments successfully captured dynamic changes in PR and pF across a wide range of soil water contents (pF 0-4.2); (2) pF values exhibited strong logarithmic relationships with PR across all soil types ($R2 > 0.95$); and (3) the regression parameters (slope a and intercept b) of the pF–ln(PR) relationship could be reliably predicted from readily available soil properties including texture class, clay content, and bulk density. Independent validation using separate datasets yielded root mean square errors of 0.14, 0.21, and 0.11 pF units for clay loam, silt loam, and sandy loam soils, respectively. This PR-based approach provides a practical, field-deployable alternative for rapid assessment of soil matric potential, particularly valuable for precision irrigation management and soil hydraulic characterization where cost and ease of measurement are important considerations.

# A complete morphological and topological description of soil pore structure dynamics during wetting-drying

**Kirill D. Tolstygin[1*], Konstantin A. Romanenko[2], Kirill M. Gerke[3]**

[1] *Laboratory of digital twins of agricultural landscapes, Dokuchaev Soil Science Institute, Moscow, Russia*

[2] *Laboratory of soil physics and hydrology, Dokuchaev Soil Science Institute, Moscow, Russia*

[3] *Center for Computational Physics, Landau School of Physics and Research, Moscow Institute of Physics and Technology, Dolgoprudny, Moscow Region, Russia*

*kirill.tolstygin@yandex.ru

**ABSTRACT**

Wetting-drying cycles significantly influence soil structure and are a major driver of its dynamics. Traditional studies employing X-ray tomography have mainly relied on classical scalar descriptors -- such as porosity, bulk density, and pore-size distribution -- to quantify these changes. However, the limited informational capacity of such metrics has recently come under scrutiny. In this work, we advocate for the use of high-information-content vector descriptors: correlation functions (CFs), pore-network models (PNMs), and persistent homology. While CFs and PNMs have already proven effective for investigating soil structural dynamics, the third method -- persistent homology -- remains relatively unexplored in soil science. Its strength lies in capturing subtle topological transformations that may be overlooked by conventional approaches.

We applied these descriptors to quantify and compare structural changes in samples from three horizons of Greyzemic Chernozem (Loamic, Pachic) under different saturation levels throughout a controlled wetting–drying cycle. XCT scanning was performed at 10 saturation points, namely: initial field moisture, pF=0.4 during saturation, full saturation, pF=0.4 during drying and pFs equal to 1.5, 1.8, 2, 4.45, 5.33 and 6.43. A total of 10 XCT scannings for each sample, together with five samples from each of three horizons, resulted in 150 examined 3D images, which then were analyzed. Our analysis provides a quantitative characterization of morphological and topological evolution during cyclic wetting and drying, revealing structural hysteresis and horizon-dependent variations in the degree of structural recovery.

We highlight the primary advantage of high-information-content metrics -- their ability to comprehensively describe soil structure -- while acknowledging their interpretative complexity, as they integrate multiple structural features simultaneously. The proposed methodology offers a robust framework for describing and comparing soil structures across scales and contributes to advancing quantitative soil structural analysis.

A key achievement of this study is the numerical evaluation of soil structural dynamics using descriptors with high information content. Although previous attempts have assessed soil's ability to return to its initial state (elastic hysteresis) they usually relied on low-information-content metrics. In current research, it was possible to estimate hysteresis using distances from three different vector metrics -- a novel approach in soil science. Studying small saturation changes during drying is easier than during wetting, which limited our analysis to a few points: field state vs. pF=1.8, and pF=0.4 during wetting and drying. Soil structure differed at these same saturation points across genetic horizons.

This research has been supported by the grant of the Russian Science Foundation, RSF 23-74-00061.

# A Mechanistic Soil-Plant Model to Assess Soil Water Accessibility

**Jan Vanderborght[1*], Andrea Schnepf[1], and Mathieu Javaux[1,2]**

[1] *Agrosphere Institute (IBG-3), Forschungszentrum Jülich, Jülich, Germany*

[2] *Earth and Life Institute, UCLouvain, Louvain-la-Neuve, Belgium*

*j.vanderborght@fz-juelich.de

**ABSTRACT**

The first step in the assessment of soil water accessibility to plants is to define accessibility. One commonly used definition of soil water accessibility is the ratio of the actual water uptake by the root system to the uptake when water is fully accessible and root water uptake is determined by the amount of energy that is available to evaporate water. This definition is applied in soil water balance models that are used for irrigation scheduling, in eco-hydrological models, and in models that simulate land surface-atmosphere, assuming that a tight relationship between soil water accessibility and soil water content in the root zone can be found. This relationship has been investigated in several studies in a 'top-down' approach by observing plant transpiration and root zone soil water content. From these studies, the impact of vegetation, meteorology, and soil on the relationship has been inferred. We raise the question whether we can derive this relationship and assess its tightness using a 'bottom-up' approach that uses basic physical understanding of flow processes in the soil-plant system and that brings together knowledge about root and soil properties across scales ranging from an individual root segment and the rhizosphere around it up to the entire root architecture and the entire soil profile. Using the multiscale modelling approach that we developed, we simulate root water uptake as a function of root system architecture, root segment hydraulic properties (which we can derive from simulations of water flow through cell tissues), root hairs, root-soil contact, soil rhizosphere and perirhizal hydraulic properties, soil hydraulic properties and soil layering, and climate. Based on these simulations, we investigate the emergent relationships between soil water accessibility and root zone soil water content. In agreement with experimental observations, we find that meteorological conditions have an important impact on soil water accessibility with decreasing accessibility when evaporation demand increases. A lower plant hydraulic conductance either due to lower root tissue conductance or lower root length, also reduces soil water accessibility. Loss of soil-root contact in dry soil had a strong impact on plant water potential but a low impact on soil water accessibility. The relationships between soil water accessibility and soil water content or water potential depended strongly on soil hydraulic properties. Interestingly, using relative available water content, i.e., relative to the available water content at field capacity, reduced the variability in this relation between soils considerably. Deriving the relationship assuming a uniform soil water distribution in the root zone resulted in an underestimation of soil water accessibility. Non-uniform water distribution in the root zone increased the accessibility of water in the root zone compared to case when the same amount of water is distributed uniformly.

# Trees' Effect on Soil Penetration Resistance Under Livestock-Forestry System in Southern Brazil

**Karina Maria Vieira Cavalieri-Polizeli[1*], Sabrina Aparecida Valente Kuka[1], Vanessa Romanoski[1], and Leandro Bittencourt de Oliveira[2]**

*[2] Department of Plant Protection and Production, Federal University of Paraná, Curitiba, Brazil*

*karina.cavalieri@ufpr.br

## ABSTRACT

Soil moisture plays a crucial role in soil penetration resistance to the roots (PR), directly affecting plant growth and their ability to access water. Studies have indicated that soil moisture may be lower near trees in Livestock–forestry systems (Glatzle et al., 2021), influencing PR. However, there are few data demonstrating such an effect. This study aimed to verify the effect of the trees on PR under the Livestock-Forestry (LF) system. The study was conducted in a clayey Oxisol located at the Canguiri Experimental Center, belonging Federal University of Paraná, Brazil. Three treatments were studied, two defined by distances from the tree rows: 4 and 8 meters, both in the LF system, referred to as LF4 and LF8, and one randomly in the Livestock system, referred to as L. Soil penetration resistance data were collected on field using a penetrometer along two transects of 36 meters in length with 12 sampling points, taken every 3 m, down to a depth of 0.35 m, totaling 24 points per treatment. Measurements were taken close to the field capacity condition. Previously, data of soil water content, obtained under a potential of -10 kPa, were 0.45, 0.34, and 0.38 $m^3\ m^{-3}$, respectively, in L, LF4, and LF8. In addition, two Teros® 10 sensors were used to obtain soil moisture data, which remained at the experimental site from October 2024 to February 2025. It was observed that, in L, the highest mean value was found (0.32 $m^3\ m^{-3}$), decreasing by 16% in LF4 (0.27 $m^3\ m^{-3}$) and 13% in LF8 (0.28 $m^3\ m^{-3}$). PR data were processed in Microsoft Excel® software, considering the confidence interval (95%). The results indicated that in the first centimeters (0–5 cm), PR was similar among treatments, with an average of 0.43 MPa. In the L system, lower PR was observed throughout the soil profile compared to the LF, with values below 2.0 MPa down to 35 cm of depth. In LF4, values were near the critical threshold of 3.0 MPa in the 5–15 cm layer, differing from LF8. However, in the deeper layers of LF4 and LF8 was similar between them at some depths. At LF8, between 10–35 cm depth, PR values remained around 2.5 MPa. Despite the significant rainfall in the area, around 61 mm during the seven days before, the lower soil moisture at field capacity under LF4 and LF8 may have contributed to the increase in PR. Concluding that the trees contributed to decreasing the soil moisture and increasing the PR, which can affect plant growth.

# Creating Pathways for Roots: Artificial Macropores through Compacted Subsoils

**Elron Wiedermann[1*] and Axel Don[2]**

[1] *Thuenen Institute of Climate-Smart Agriculture, Braunschweig Germany*

*Elron.Wiedermann@thuenen.de

**ABSTRACT**

Soil compaction has adverse impacts on key soil functions, including the restriction of root growth into depth. However, the presence of vertical macropores facilitates access to water and nutrient reservoirs in subsoils. While mechanical amelioration strategies are susceptible to recompaction, bio-drilling with taprooted perennial crops or earthworms has been shown to be limited meliorating compacted layers. This highlights the need for novel remediation strategies. Therefore, the use of artificial macropores as preferential pathways into the subsoil, particularly under compacted soil conditions, may restore soil functions and increase plant productivity. The objective of the present study was to assess the colonization of artificial pores with roots and anectic earthworms, as well as the effect on root depth development and yield of cereals. It is hypothesized that there will be a positive influence on root depth distribution and yield under dry growing conditions.

Two randomized and four times replicated field trials were setup in 2024 at farmers field sites in Northeastern Germany (treatments: Control and 100 artificial pores $m^{-2}$) and Central Germany (treatments: Control, 50, 100, and 200 artificial pores $m^{-2}$). In total 11.500 artificial macropores, 10 mm in diameter, were manually created down to 80 cm depth. Sampling took place in 2024 and 2025. Convolutional neural network-based image analysis was employed to analyze root depth distribution within 0-100 cm.

Across both years artificial pores led to an increase in yield by 12% for the 100 pores per square meter treatment on the loamy sand and by 2%, 3%, 5% for the 50, 100 and 200 pores per square meter treatment on the silt loam. In subsoils beneath the compacted plow horizon the artificial pores increased root length density in 50-100 cm soil depth by 110%. Results indicated higher attractiveness of artificial pores, as 88% of them were colonized with at least one root, while only 73% of biopores were colonized with roots. In 2024, 1.4% and in 2025, 3.5% of artificial pores were already colonized by anecic earthworms on the silt loam.

These findings indicate that artificial macropores constitute a promising strategy to enhance root depth distribution, water and nutrient uptake and finally yields, in soils characterized by compaction.

## ABSTRACT

Modeling plant water and nutrient uptake is a cornerstone of understanding the **Soil-Plant-Atmosphere Continuum (SPAC)** and is critical for optimizing agricultural productivity and environmental sustainability. Among the various numerical tools available, the HYDRUS software package (Šimůnek et al., 2024) has emerged as one of the most robust and widely used platforms for simulating these complex processes. This ABSTRACT explores the mechanisms, mathematical frameworks, and practical applications of modeling plant water and solute uptake using HYDRUS.

**Plant Water Uptake**

HYDRUS simulates water flow in variably saturated porous media by numerically solving the **Richards equation**. Plant root water uptake (RWU) is incorporated into this equation as a **sink term (*S*)**. The potential transpiration rate is distributed across the root zone based on the root length density distribution. However, actual water uptake is often lower than potential uptake due to environmental stresses. HYDRUS employs two primary modeling approaches to describe this reduction. On the one hand, it uses an empirical macroscopic model of Feddes et al. (1978). On the other hand, it implements three physically based models of Nimah & Hanks (1973), Couvreur et al. (2012, 2014), and de Jong van Lier et al. (2008, 2013). All three physically based RWU models can simulate processes such as hydraulic lift or compensated RWU. The model further accounts for **salinity stress** by integrating osmotic potential into the response functions. This is particularly vital in arid regions where irrigation with marginal-quality water is common.

**Plant Solute and Nutrient Uptake**

Beyond water, HYDRUS simulates the transport and uptake of solutes (e.g., nutrients like nitrates or contaminants) (Šimůnek and Hopmans, 2008). The model distinguishes between two primary mechanisms. A) **Passive Uptake:** Solutes are carried into the root system via the mass flow of water. B) **Active Uptake:** This accounts for the plant's physiological ability to absorb nutrients against concentration gradients, often modeled using **Michaelis-Menten kinetics** or specific concentration thresholds.

**Dynamic Plant Uptake Modules**

Soil pollution from neutral and ionizable compounds poses a significant threat to water resources management and food production. To address this problem, HYDRUS was coupled with a multi-compartment dynamic plant uptake model (Brunetti et al., 2019, 2021, 2022), which accounts for differentiated multiple metabolization pathways in plants' tissues. The model, which can simulate the reactive transport of neutral compounds, has been successfully validated against experimental data. HYDRUS has also been coupled with the SUGAR model (Brunetti et al., 2025), which predicts water and carbohydrate distribution within the soil-fruit system. The model can provide insights into water and carbohydrate allocation under different watering regimes, advancing predictive capabilities for sustainable crop management strategies.

**Applications and Significance**

By coupling these uptake mechanisms, HYDRUS enables researchers to predict the efficiency of fertigation, the risks of nutrient leaching to groundwater, and the impact of climate change on crop water requirements. The software's ability to handle multi-component chemistry through the **UNSATCHEM** module makes it indispensable for managing soil sodicity and salinity. Ultimately, modeling with HYDRUS provides a mechanistic understanding that bridges the gap between small-scale soil physics and field-scale agricultural management.

# Biochar application to soil in agricultural water management

**ABSTRACT**

The problem of water shortage in agricultural production is becoming more and more noticeable, even in those parts of the world where water shortages have not occurred. Climate change, increasingly dynamic weather, and extreme phenomena such as droughts and floods pose a significant threat to the agricultural production process and its future planning. Therefore, it is essential to develop new strategies and water-saving technologies that will better enable farmers to address the challenges of modern agriculture. The FARMWISE project is dedicated to finding new solutions and tools for decision-making in the field of water management strategies and tackle the pressing challenges of water scarcity and quality in agriculture. One of the solutions being tested is the production and use of biochar as a soil additive that improves soil water properties and water retention capacity. The task aimed to invent and implement a simple tool for biochar production on-site at the farm. As well as testing the obtained biochar in field conditions and monitoring the effect of the additive on the quantity and quality of water available to plants. The results of field experiments conducted in the arable field and in the apple tree orchard clearly indicate an improvement in the sorption properties of the soil, including the ability to retain water, as well as an improvement in other soil parameters that are important for the development of the plant root system and the uptake of nutrients introduced with fertilization and irrigation. The use of 10t/ha of biochar increased water retention capacity by up to 10% in sandy soil and reduced water runoff from the soil under constant plant irrigation, which contributes to lower production costs and reduces the negative impact of agricultural production on the environment.

**ABSTRACT**

Irrigation is essential for sustaining crop productivity and agricultural sustainability in saline–alkali farmlands, but it also intensifies the contradiction between freshwater supply and demand in water-scarce regions. In the Yellow River Delta (YRD), widely distributed saline soils with pronounced spatial–temporal heterogeneity and shallow saline groundwater strongly alter water–salt dynamics in the crop root zone. This results in large regional differences in unit irrigation water consumption (UIWC), creating challenges for accurately estimating regional irrigation demand and optimizing cropping structures to reduce irrigation pressure. Hydrological, meteorological, soil, and crop growth data of the YRD from 2021 to 2022 were collected using ArcGIS 10.8.2. Five dominant cropping structures across 17 townships—winter wheat–summer maize, winter wheat–summer soybean, rice, and cotton—were selected as research objects. The HYDRUS-1D model was employed to quantify the UIWC under current cropping systems, and spatial distribution maps of UIWC and regional water use efficiency (WUE) were generated. The results indicated that the pre-sowing root-zone salt leaching requirement across the entire region ranged from $1.13 \times 10^8$ to $1.59 \times 10^8$ m³, showing a significant discrepancy compared with estimates derived from empirical formulas. Substantial spatial variation in unit irrigation water consumption (UIWC) was observed among townships, with coastal areas requiring considerably higher irrigation due to higher soil salinity and more saline shallow groundwater. In some moderately to severely saline soils, the pre-sowing leaching requirement for summer maize–winter wheat and spring maize even exceeded the irrigation demand during the growing season. Grain crops (wheat and maize) exhibited the highest irrigation demand, accounting for 79.3% of the total, whereas cotton required the least (11.4%) owing to its strong salt tolerance and the coincidence of its growing season with the regional rainy period. Overall, the total irrigation demand under the current cropping structure reached $6.65 \times 10^8$ m³, whereas the actual water supply was only $2.7 \times 10^8$ m³, resulting in a substantial deficit of approximately $3.9 \times 10^8$ m³. These findings demonstrate that, under the current cropping structure, the YRD is highly vulnerable to irrigation deficit, yield reduction, and aggravated soil salinization. Optimizing cropping structures and improving irrigation efficiency are therefore critical strategies to alleviate regional water scarcity, safeguard food security, and promote sustainable agricultural development in saline–alkali regions.

# Stress-Strain Mechanism of Salt-affected Soils in the Yellow River Delta

**ABSTRACT**

The continuous increase in agricultural mechanization has led to intensified soil compaction degradation. It is crucial for ensuring the sustainable development of national agriculture by addressing soil compaction. Salt-affected soils, which are important reserves for arable lands, have experienced an increase in agricultural use in response to national demand in China, leading to an increased soil compaction risk. However, current research on soil compaction is mainly focused on non salt-affected soils, resulting in a lack of understanding of the compaction process under salt-affected soils. To address this gap, this project will focus on the Yellow River Delta farmland ecosystem. By a combination of incubation experiment, field experiments, and model simulation, this report aims to talk the following objectives: 1) Study the stress distribution, transmission, and soil strain characteristics of soil mechanical compaction process in farmland with different saline gradients. This will clarify the salt-affected soil compaction process and reveal the mechanism behind salt-affected soil compaction. 2) Based on the soil stress-strain characteristics of the study area, combine the annual seasonal dynamics of soil moisture and the development trend of farming machine types, it will enable the construction of a soil compaction model of the study area and predict the spatial and temporal trends of soil compaction risk in regional farmlands. The research results will have significant scientific and practical value in understanding the occurrence mechanism of soil compaction and prevention of farmland risk in the Yellow River Delta.

# Impact of drought and root excision on root regeneration, xylem hydraulics and leaf physiological characteristics in Robinia pseudoacacia

**Min Li[1*], Haoyan Wei[1]**

[1] *Northwest A&F University (College of Water Resources and Architectural Engineering, Yangling, China)*

*limin2016@nwafu.edu.cn

**ABSTRACT**

Underground mining subsidence can induce alterations in the vadose zone structure, resulting in direct root damage and a reduction in available water, which pose threats to plant survival. Nevertheless, the impacts of these stress factors on root xylem hydraulic conductivity and leaf water metabolism still remain ambiguous. This study explored the influences of different drought intensities (no drought, moderate, severe) and root excision intensities (0%, 25%, 50%) on the root characteristics, xylem hydraulic conductivity, and leaf physiology of Robinia pseudoacacia. The results show that the fine root length and fine root mass fully recuperated to pre-stress levels within one month under all treatment conditions at the whole-plant scale. However, density-based analysis indicated that stress augmented fine root proliferation in the non-excised area, and root excision predominantly regulated fine root length density and fine root mass density. The percentage loss of xylem hydraulic conductivity, maximum xylem specific hydraulic conductivity, leaf water potential, and leaf gas exchange parameters were influenced by drought stress and root excision. Relative contribution analysis indicated that drought stress exerted the most substantial influence on xylem hydraulic characteristics. Conversely, regarding leaf physiological properties, apart from the effect of drought stress, the interaction between drought stress and root excision also made a notable contribution. Overall, fine root regeneration alleviated the impacts of excision, emphasizing soil water deficit as the key limiting factor. Considering that most coal resources are situated in arid regions and the drought is intensifying due to climate change, giving priority to drought mitigation is essential for preventing post-subside vegetation degradation.

**ABSTRACT**

The current processes of climate change, as well as agriculture, lead to both positive and negative changes in soil health. To prevent the negative impacts of soil degradation and to restore degraded soils, practice-oriented solutions are needed for sustainable food production as well as for the quality of environmental services. This requires knowledge of how soil water regimes are formed, including the control of infiltration and runoff, the effects of water erosion, deep percolation, and lessivage. Recent advances in understanding the relationship between soil hydrological and biogeochemical processes allow for further improvement of models that link soil water regimes and hydraulic functions, depending on soil structure, texture, and organic matter content (SOM).

In this context, it is of considerable interest to model the effect of changes in SOM on soils with different structures and textures regarding the amount of water available for agricultural plants. To this end, a previously proposed model for estimating soil water retention (SWR) based on the additivity hypothesis was improved by including two parameters: SOM and the density of soil aggregates. To verify this model, we used datasets from laboratory experiments conducted on samples with Montluel soil monoaggregates, as well as samples of soil aggregates.

The analysis of results obtained from Montluel soil samples allowed us to test the effects of soil compaction on interaggregate and intraaggregate porosity, as well as their influence on SWR. Testing the model on samples of aggregate fractions enabled us to examine the effects of soil aggregate size on interaggregate and intraaggregate porosity, as well as on SWR. Additionally, using datasets of SWR included in the UNSODA database, we compared the results of the improved model with those obtained from several common regression models known as pedotransfer functions for estimating SWR.

It was shown that the effect of SOM on SWR is not uniform across different soil textures. For soils with coarse textures, the influence of SOM leads to more significant changes in SWR than for soils with a high content of fine fractions. Thus, the results indicate, on one hand, an improvement in the predictive description of SWR using an enhanced additive model, and on the other hand, highlight the need for further research—especially by distinguishing between two fractions of SOM: particulate organic matter and mineral-associated organic matter.

*E-mail Address of Presenting Author: huanglm@igsnrr.ac.cn

**ABSTRACT**

Understanding the water use patterns of artificially revegetated plants in arid and semi-arid desert regions with shallow groundwater is crucial for sustainable water resource management and effective vegetation restoration strategies. Despite extensive vegetation rehabilitation in China's Mu Us Sandy Land, the interspecific and seasonal variations in plant water sources under similar groundwater conditions remain unclear. We conducted isotopic analysis of hydrogen and oxygen in main sand-fixing plants—*Pinus sylvestris var. mongolica*, *Amygdalus pcdunculata Pall*, and *Artemisia desertorum Spreng*—alongside potential water sources during the three growing seasons. Our aim was to elucidate seasonal changes in plant water uptake patterns by correcting isotopic offsets in xylem water using the MixSIAR model. Results indicated that *A. desertorum* predominantly utilized water from the 0–150 cm soil layer (67.52±14.44 %) throughout all seasons. Conversely, P. sylvestris and *A. pedunculata* shifted their primary water sources from the 60–240 cm soil layer during the dry season (55.20±2.12 and 57.96±1.45 %, respectively) to the 0–150 cm soil layer during the rainy season (68.44±4.46 and 66.19±1.68 %, respectively), suggesting greater water uptake adaptability in trees and shrubs compared to grasses. Groundwater contribution to plant water uptake showed no significant interspecies difference during the rainy season ($P > 0.05$). However, *P. sylvestris* and *A. pedunculata* significantly increased groundwater absorption during the dry season compared to the rainy season ($P < 0.05$). Correcting $\delta^2H$ offsets in xylem water revealed an underestimation of groundwater contributions by 16.06±9.09 % in the dry season and 4.25±0.55 % in the rainy season. Given these interspecific and seasonal variations in water uptake patterns among sand-fixing plants, and the imperative for sustainable groundwater use, tailored water management strategies are essential to prevent the degradation of restored ecosystems in this water-limited desert region.

## ABSTRACT

Salt precipitation, a common phenomenon in saline soils, significantly influences water and heat transport—a subject that has attracted considerable research attention. However, the specific mechanisms and effects of salt precipitation on these processes remain unclear. In this study, we investigate the evolution of salt precipitation and its impact on evaporation and soil temperature under varying soil textures, evaporation demands, salt types, and hydraulic conditions, using combined experimental and numerical simulation approaches. Results show that salt crust patterns vary with soil texture. In finer-textured soils (silt loam), thin, flat, and uniform salt crusts develop, offering greater resistance to evaporation. In contrast, coarser soils form thick, rough salt crusts with lower evaporation resistance. Sodium sulfate tends to precipitate as sub-florescence during soil drying, whereas sodium chloride primarily forms efflorescence. Under high evaporation demand, fine powder-like crystals precipitate uniformly, while under low evaporation demand, discrete and larger crystals are observed. Salt crusts notably increase soil temperature, with temperature dynamics being closely linked to crust evolution. The elevated temperature in saline soils compared to salt-free soils is attributed to several factors: reduced heat loss due to higher evaporation resistance and lower surface emissivity of the salt crust, very low thermal resistance of the crust itself, heat release during saline solution crystallization, and lower soil heat capacity. These findings enhance the understanding of water and heat balance in saline soils under evolving salt precipitation conditions.

# Field-scale Assessments of Subsoil Compaction and Soil Structural Functions in Lower Saxony, Germany

*xinjun@ifbk.uni-hannover.de

**ABSTRACT**

Subsoil compaction a one of the major threats for crop production and soil ecological functioning in Europe. To quantify its field-scale extent, field investigations were conducted on 26 agricultural fields across Lower Saxony state in northern Germany, covering four dominant soil textures (clay loam, sandy loam, silt, and silty loam) and two field management zones (machinery turning area and main field area). In-situ measurements of penetration resistance and shear strength were conducted on field at 10 cm (topsoil) and 40 cm (subsoil), and bulk density (ρb), saturated hydraulic conductivity (Ks), air permeability (Ka) were measured on undisturbed soil samples at the same depth. The results showed that most machinery turning zones showed clear signs of subsoil compaction. About 80% fields showed 5~60% higher penetration resistance and shear resistance in machinery turning area. For sandy loam soil in the east and north part of Lower Saxony, penetration resistance frequently exceeded 3 MPa, reaching >5 MPa at 40 cm, which is above root limiting thresholds. Compared to main field zone, bulk density in machinery turning area increased by 2-5%, with silty loam field exhibiting the largest increase of bulk density. Additionally, soil pore functions of Ka and Ks in machinery turning area exhibited obvious decline compared to field area especially in the subsoil of silty loam and sandy loam fields. For both machinery turning area and field area, a significant correlation was found between hydraulic conductivity and soil bulk density (R2=0.21, p=0.023) in topsoil with ρb from 1.25~1.60 g cm-3, while in subsoil with ρb from 1.45~1.65 g cm-3 no such correlation was found, indicating the pore functions in subsoil mainly depends on connective pores during the structure formation process. These results demonstrate that traffic-induced subsoil compaction is widely altering soil physical structure and pore functions in Lower Saxony, and the texture-dependent responses highlight the need for specific compaction mitigation strategies during the future field managements.

## ABSTRACT

Freshwater scarcity is a preeminent global challenge, with agriculture alone accounting for 70% of total consumption. A soil's capacity to retain water, filter solutes, and recharge aquifers is dictated by its **Soil Water Retention Curve (SWRC)**. As a fundamental property in soil physics, the SWRC—alongside pore size distribution—is essential for modeling fluid and solute transport within the vadose zone. These properties have critical implications across agriculture, forestry, ecology, and civil engineering.

**The Current Bottleneck**

Despite their importance, quantifying soil hydraulic properties remains a significant challenge. Conventional empirical methods, such as porous plates and pressure cells, are:

- **Laborious and time-consuming:** Often taking days or weeks.
- **Expensive:** Requiring specialised, high-maintenance equipment.
- **Prone to error:** Susceptible to operator bias and experimental inaccuracies.

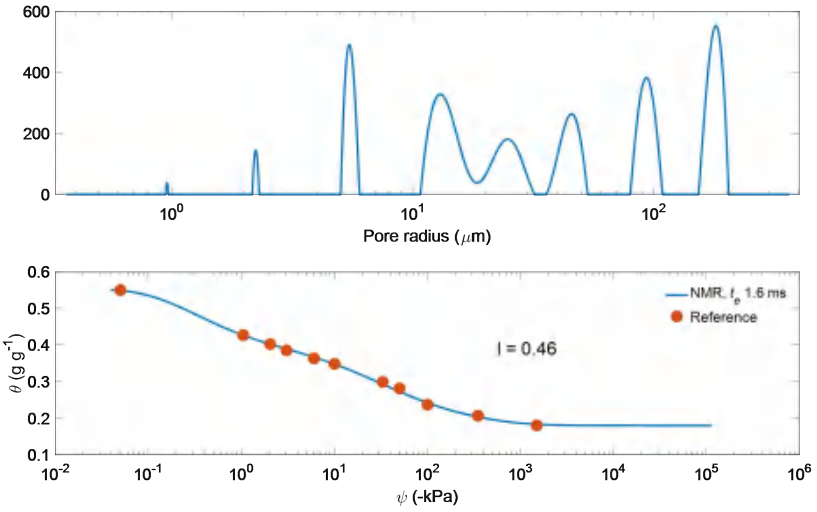
These limitations make hydraulic characterisation the primary bottleneck in soil physics laboratories worldwide.

**A New Analytical Frontier: NMR Relaxometry**

While $^1$H Nuclear Magnetic Resonance (NMR) relaxometry has been used to characterise soil porosity, it often presents an "ill-posed problem." Traditional spin-lattice and spin-spin relaxometry results are confounded by two correlated unknowns: **pore length scales** and **surface relaxivity**.

To overcome this, we propose a method that directly accesses **NMR diffusion modes**. This approach is governed solely by pore size, making it independent of unknown surface relaxivity. Our refined low-field NMR method is:

- **Fast:** Delivers results in under 90 minutes.
- **Precise:** Provides unprecedented resolution and accuracy.
- **Comprehensive:** Simultaneously determines pore size distribution, the SWRC, and hydraulic conductivity.



**Validation and Results**

We evaluated an optimised, more robust and elegant pulse sequence on 21 challenging soil samples (including Gleyic and Vertic). After saturation and thermal stabilisation, the samples were analysed using the **DIFF method**. The results confirm that this approach accurately determines pore size distribution and estimates water retention curves in a fraction of the time required by conventional techniques (Figure).

**ABSTRACT**

Soil-plant water transport is a fundamental hydrophysiological process in terrestrial ecosystems. While factors influencing this process under drought stress have been increasingly identified, their interactive effects remain poorly understood. In this study, we combined literature synthesis with a process-based soil-plant water transport model to investigate how key hydraulic traits, including stomatal sensitivity, soil texture, and plant hydraulic vulnerability, jointly shape plant drought responses. In particular, we focused on how the combined effects of these traits influence the relationship between soil and leaf water potentials ($\psi_{soil}$-$\psi_{leaf}$), mediating the expression of isohydric versus anisohydric strategies. Our results demonstrate that plants with greater stomatal sensitivity to $\psi_{leaf}$ also respond more strongly to variations in $\psi_{soil}$ and exhibit smaller reductions in soil-plant hydraulic conductivity($K_{sp}$). Beyond stomatal sensitivity, rhizospheric hydraulic conductivity ($K_{rhizosphere}$) influences soil-plant water transport, and its influence varies with soil texture. The higher hydraulic conductivity of loam soils compared with sand soils amplifies the influence of $K_{rhizosphere}$ variability on transpiration, stomatal conductance, and $K_{sp}$. The $\psi_{leaf}$-$\psi_{soil}$ relation shows plants characterized by low stomatal sensitivity, high vulnerability in $K_{sp}$, and sand soil planting conditions tend to exhibit greater divergence between $\psi_{leaf}$ and $\psi_{soil}$, leaning towards an anisohydric behavior. These findings suggest that the $\psi_{leaf}$-$\psi_{soil}$ relation arises not from individual hydraulic components in isolation, but from their integrated interactions. This underscores the importance of a systems-level perspective in soil-plant water transport and supports the development of integrative frameworks to better predict plant responses under intensifying drought conditions.

## ABSTRACT

Plants respond to soil and atmospheric water deficits through strategies such as stomatal regulation and belowground adaptations. Root mucilage buffers erratic fluctuations in rhizosphere water content, yet its influence on soil hydraulic properties, especially unsaturated hydraulic conductivity, and stomatal regulation remains unknown. We hypothesized that mucilage facilitates water uptake by attenuating the drop in matric potential at the root-soil interface during soil and atmospheric drying. We measured the impact of various maize mucilage contents (0.0%, 0.05%, 0.2%, and 0.4%) on the water retention and hydraulic conductivity of a loamy soil. Leveraging a soil-plant hydraulic model, we investigated the effects of mucilage contents on transpiration and stomatal responses under soil drying and increased vapor pressure deficit (VPD). Higher mucilage contents prevented sharp declines in unsaturated hydraulic conductivity as soils dried. Simulations revealed that higher mucilage contents delayed the onset of hydraulic stress (the threshold transpiration rate beyond which small increase in transpiration would result in a disproportional decline in leaf water potential), broadened the hydroscape zone, and shifted stomatal behavior from isohydric to more anisohydric regulation, enabling plants to sustain stable transpiration and lower midday leaf water potentials under drought. The buffering effects on soil-plant hydraulics were persistent across varying VPD, although high mucilage contents accelerated soil drying, indicating a trade-off between improved water uptake and faster moisture depletion during prolonged drought. Our findings underscore the important role of mucilage in modulating soil-plant water relations and stomatal regulation, offering insights into strategies for improving plant response to soil and atmospheric drought.

## ABSTRACT

Wetlands play an irreplaceable role in climate regulation, water conservation, and biodiversity protection, earning them the title of "kidneys of the Earth." Coastal wetlands, located in the land-sea ecotone and subject to the interactive forces of terrestrial and marine processes, are highly sensitive to external disturbances and represent globally sensitive and fragile ecosystems under environmental change, exhibiting distinct regional characteristics. The Yellow River Delta, as the world's most intact, typical, and youngest warm temperate wetland ecosystem, is situated in a unique geographical location where land, sea, and river interactions occur. This has led to the formation of a notably ecologically vulnerable and sensitive zone, characterized by high dynamism and complexity, making it representative on a global scale.

Tamarix chinensis, as a dominant and constructive species in the Yellow River Delta, possesses traits such as salt tolerance, alkali tolerance, resilience to barren soils, and drought resistance. It serves as a pioneer and key species for saline-alkali land improvement and ecological restoration in coastal wetlands of the region. However, existing research has largely focused on the growth characteristics and stress resistance physiology of Tamarix chinensis, with limited systematic investigation into its water-use strategies and sources. In recent years, hydrogen and oxygen stable isotope techniques have been widely applied in studies of plant water sources due to their minimal destructiveness to plants and high data reliability. Except for a few xerophytic and halophytic plants that may exhibit hydrogen stable isotope fractionation during root water uptake, most plants do not undergo stable isotope fractionation. Therefore, by comparing the stable isotope values of plant stem xylem water with those of potential water sources, the proportional contributions of various water sources to plant uptake can be estimated.

Accordingly, this study takes Tamarix chinensis populations at different land-sea locations in the Yellow River Delta as research subjects. Using stable isotope techniques, we measure the spatial variations in $\delta^2H$ and $\delta^{18}O$ values in xylem water of Tamarix chinensis and potential water sources. The MixSIAR model is employed to calculate the contribution proportions of potential water sources to Tamarix chinensis, aiming to investigate the adaptation mechanisms of Tamarix chinensis to varying water conditions across different habitats.

The Yellow River Delta (36.33°N–38.10°N, 117.19°E–119.11°E), situated in northeastern Shandong Province and bordering the Bohai Sea and Laizhou Bay, is the largest, youngest, and most rapidly developing typical river estuary delta in China. This study focuses on its eastern coastal area and the Yellow River estuary region (37°40′–38°10′N, 118°41′–119°16′E). The area experiences a warm-temperate semi-humid continental monsoon climate, characterized by four distinct seasons with pronounced differences in temperature and humidity between cold/dry and hot/wet periods. The mean annual temperature is 12.6°C, and the mean annual precipitation is 543.2 mm.The Yellow River, as the primary exogenous river, serves as the main source of freshwater resources for the region. The groundwater table is shallow (1–2 m) with high salinity, generally ranging from 5 to 20 g/L. Its main recharge sources are precipitation, river infiltration, and lateral seawater intrusion. The terrain is predominantly low-lying (mostly below 15 m in elevation). Seawater intrusion and lateral infiltration contribute to a raised groundwater table, which readily triggers soil salinization.

Influenced by factors such as historic shifts of the Yellow River course and marine erosion, the soils are primarily Fluvo-aquic soils and Saline soils. Saline soils are distributed in a belt-like pattern along the coast, accounting for 36.16% of the total soil area, with surface soil salt content ranging from 0.8% to 2.0%. Sandy soils are predominant along the Yellow River banks, gradually transitioning to loam and clay soils inland.Within the study area, the halophyte Tamarix chinensis is widely distributed. It is frequently associated with companion species such as Suaeda glauca, Suaeda salsa, Phragmites australis, Artemisia scoparia, Sonchus wightianus, Setaria viridis, and Cynanchum chinense.

In the eastern region of the Yellow River Delta, six typical, continuous, and minimally human-disturbed Tamarix populations (aged 8–10 years) were selected along the Yellow River and near its estuary. These sites, labeled sequentially from sea to land as A, B, C, D, E, and F (Fig. 1), were equipped with two sets of thermal dissipation probes (TDP-30, Dynamax Inc., Houston, Texas, USA) installed in the 0–90 cm soil layer beneath the Tamarix canopy at each site prior to the initiation of field research. The probes were used for hourly automated monitoring of soil moisture and electrical conductivity. Additionally, a groundwater observation well was installed near the center of each site to monitor groundwater dynamics, and global positioning system (GPS) coordinates were recorded for all sampling locations.

During the peak growing season of the shrubs, investigations were conducted on Tamarix populations near the probe installations. Uniformly growing individuals were selected at each site, and root samples were collected using a root drilling method at three directions 30 cm from the base of each plant. An 85 mm diameter root drill was employed to collect samples at intervals of every 10 cm within the 0–50 cm depth and every 20 cm below 50 cm, down to a depth of 130 cm. Simultaneously, a soil profile of 1.3 m depth was excavated at each site, and 100 $cm^3$ soil cores as well as stratified soil samples were collected following the same depth intervals. In each quadrat, select three Tamarix plants and collect fully suberized two- or three-year-old branches from each plant. Using pruning shears, excise the branches into 5-cm segments, remove the phloem, and retain the xylem. Immediately place the segments into a capped glass sample vial and seal the opening with Parafilm. Repeat this sampling procedure three times per sampling point. Within a 1-m radius around each selected Tamarix individual, collect soil samples with a 4.5-cm diameter auger from the following depth intervals: 0–20 cm, 20–40 cm, 40–60 cm, and 60–100 cm. Transfer the collected soil samples promptly into capped glass vials. Simultaneously, collect groundwater samples and seal all vials with Parafilm. Subsequently, store the plant and soil samples at –10 °C, and preserve the groundwater samples at 4 °C.

All soil and plant samples were transported to the laboratory for systematic physicochemical analysis.

Based on the comparison of isotopic signatures between soil water and plant xylem water, the ranges where their isotopic values are similar or overlapping can be considered as potential water sources for the plants. As shown in Figure 2, influenced by their varying distances from the river and the sea, the water-use strategies of Tamarix plants differ across sampling sites. At site A, Tamarix primarily absorbs soil water from around the 50 cm depth. With decreasing distance from the Yellow River, the water source for Tamarix at site B shifts gradually toward the 50~100 cm soil layer. The xylem water isotopes of sites D and C show significant overlap with those of shallow soil water at 20~60 cm, indicating that these sites mainly rely on water from this layer. In contrast, Tamarix at site E predominantly utilizes deeper soil water from the 60~100 cm layer. Meanwhile, at site F, the xylem water isotopes overlap repeatedly with soil water isotopes across the 20~100 cm profile, suggesting that Tamarix at this site exploits water more evenly from different soil depths.

Due to the occurrence of hydrogen stable isotope fractionation during water uptake by roots of xerophytic or halophytic plants, while oxygen stable isotopes do not fractionate, this study used only $\delta^{18}O$ values to calculate the water contribution ratios. As shown in Figure 3, the proportion of water use from different soil layers by Tamarix plants exhibited significant spatial heterogeneity across the sampling sites. Overall, the contribution ratios of the 0–20 cm, 20–60 cm, and 60–100 cm soil layers ranged from 11.1% to 33.0%, 28.3% to 60.6%, and 28.3% to 53.0%, respectively. At the individual site level, water use patterns varied distinctly with depth: sites A, B, C, and E showed the lowest contributions from the shallow 0–20 cm soil layer, at 11.1%, 20.9%, 21.9%, and 17.6%, respectively. Among these, site A recorded the highest contribution from the 20–60 cm layer (60.6%), while sites B and C also peaked in this layer (39.1% and 40.4%, respectively). In contrast, site E derived its highest water contribution from the 60–100 cm layer (53.0%). Site D exhibited the lowest contribution from the 20–60 cm layer (28.3%) and the highest from the 60–100 cm layer (42.9%). Site F demonstrated relatively even water uptake across depths, with a cumulative contribution from the 0–60 cm layers (0–20 cm + 20–60 cm) of 66.2%, which was higher than that from the 60–100 cm layer (33.8%). In summary, site F relied predominantly on shallow soil water, site A primarily utilized water from the 20–60 cm layer, and site E showed a pronounced dependence on the middle to deep soil water (60–100 cm), reflecting its distinctive water acquisition strategy.

Based on the relationships among root distribution, water sources, and soil water–salinity environments at various sampling sites (Fig. 4), the water uptake strategies of Tamarix plants differed markedly across locations. At site A (7.78 km from the river, 20.73 km from the sea), where influence from both river and sea was weak, the shallow soil moisture was only 28.24% and salinity reached 15.52 $g \cdot kg^{-1}$, creating pronounced water and salt stress. This led to reduced root proliferation in shallow soil and concentration of roots in the 20–60 cm layer. As a result, water uptake from shallow soil was minimal (11.1%), while uptake from the middle layer accounted for 60.6% of the total, reflecting an avoidance strategy under high salinity and low water availability in surface soil.

At site B (0.32 km from the river, 22.03 km from the sea), located close to the Yellow River, balanced water–salt conditions supported relatively uniform root distribution in the middle to deep layers (20–100 cm), with similar water uptake proportions from these layers (39.1% and 39.9%). Site C (4.77 km from the river, 14.29 km from the sea), situated in a zone with moderate river and sea influence, exhibited mild water–salt conditions. Roots were distributed relatively evenly in the 20–100 cm profile, and water uptake proportions across layers were comparable (21.9%, 37.7%, and 40.4%), with only slightly lower uptake from the surface due to elevated salinity.

At site E (9.21 km from the river, 7.02 km from the sea), distant from the Yellow River and with limited freshwater recharge, vertical differentiation in water and salt conditions was pronounced. Roots extended significantly into the deep layer (60–100 cm), where water uptake reached 53.0%. Site F (0.31 km from the river, 1.22 km from the sea), influenced by both river freshwater and seawater intrusion, showed even root distribution in the 20–100 cm profile, with nearly equal water uptake from shallow, middle, and deep layers (33.0%, 33.2%, and 33.8%).

Site D (3.15 km from the river, 6.30 km from the sea) lies in a sensitive river–sea interaction zone. Surface soil (0–20 cm) salinity was as high as 19.91 $g \cdot kg^{-1}$, imposing strong salt stress, while the deep layer (60–100 cm) exhibited favorable conditions with 52.34% moisture and reduced salinity (15.90 $g \cdot kg^{-1}$). Correspondingly, roots extended substantially into the 60–100 cm layer, from which water uptake contributed 42.9% of the total—thereby avoiding high surface salinity while accessing stable water from deeper soil.

Overall, these patterns illustrate how root distribution and water uptake strategies in Tamarix are direct responses to local water–salt conditions shaped by varying distances from the river and the sea.

This study reveals that the varying distances from the river and the sea in the Yellow River Delta shape heterogeneous hydro-salinity conditions, which further influence the root distribution and water-use strategies of Tamarix plants. In areas close to the river, where water and salinity conditions are relatively balanced, roots are evenly distributed in the middle to deep soil layers, allowing for balanced water uptake across different depths. In coastal zones and river-sea interaction areas, high surface salinity drives root proliferation into deeper soil layers, leading to a preferential use of deeper, low-salinity water. In sites distant from both the river and the sea, dual stressors of water scarcity and salinity lead to roots concentrating in the middle soil layers where moisture conditions are more favorable, resulting in a water-use pattern centered on middle-depth soil water. Tamarix thus adapts to local hydro-salinity stress through plasticity in rooting depth. The findings provide theoretical support and practical guidance for the conservation and ecological restoration of wetland vegetation in the Yellow River Delta.

**ABSTRACT**

The Yellow River Delta faces severe soil salinization challenges driven by shallow groundwater tables and intensive evaporation. Conventional flood irrigation (FI) not only results in significant water wastage but also exacerbates the salinization process. Saving water and controlling salt is an important means to solve practical problems in local agriculture. The advantages of drip irrigation(DI) in water saving and salt control have been widely confirmed in recent years, but there is still a lack of in-depth research on the regulatory effect of soil compaction(SC) on water and salt migration, especially its synergistic mechanism with drip irrigation.This study used soil data collected from two consecutive years of cotton field experiments to obtain soil hydraulic parameters and solute transport parameters through the construction of a Hydrus-2D model. Three simulation scenarios were established:FI, FI+SC, and DI+SC. It has been verified that the model parameters can better simulate the soil water and salt migration in the cotton root zone in this area.Simulation results show that SC reduces soil hydraulic conductivity by reducing soil pores, inhibiting the capillary rise of deep high-salinity groundwater, thereby reducing evaporation and salt return. However, FI+SC was prone to prolonged surface ponding, which hindered effective root water uptake. In contrast, the DI+SC configuration, characterized by a low-flow and high-frequency irrigation regime, delivered water directly to the crop root zone. It reduces the waste of water resources caused by evaporation and improves water utilization efficiency. At the same time, the compacted layer can prevent deep high-salinity groundwater from going up, and the effect of water saving and salt control is significant. The results of this study can provide scientific basis and decision-making support for water conservation and salt control in saline-alkali farmland in the Yellow River Delta region.

## ABSTRACT

Soil heat flux plates (SHFPs) are widely used for measuring soil heat flux ($G$); however, they are prone to significant errors due to differences in thermal conductivity between the plate and soil, thermal contact resistance, and water flow divergence. This study synthesizes findings from two methodological approaches—laboratory-based physical correction and field-based empirical calibration—to evaluate the effectiveness of improving SHFP accuracy.

First, the application of the **Philip correction** was evaluated using laboratory experiments with agar-stabilized water to eliminate thermal contact resistance. Results showed that manufacturer-specified thermal conductivity values ($\lambda_p$) and plate dimensions often deviated from measured values. The Philip correction, particularly using the full plate geometry function ($H$), improved the estimation of $G$ for plates with thermal conductivities mismatched to the medium. However, in field conditions under a full maize canopy, the Philip correction only partially reduced errors. While using measured $\lambda_p$ and the full $H$ expression improved agreement with the References gradient method, significant underestimations (38%-62%) persisted due to unaccounted factors like variable soil-plate contact.

Second, a **field calibration method** was assessed as a comprehensive solution. This method utilized a short calibration period (5 days) to determine a correction coefficient based on the ratio of raw plate measurements to the References soil heat flux ($G_{s_grad}$). Remarkably, this simple linear correction accounted for almost all types of errors (including contact resistance and heat flow divergence). When applied to evaluation periods of 60–80 days, the field-calibrated values ($G_{p_corr}$) showed excellent agreement with $G_{s_grad}$ , with slopes approaching 1:1 and RMSE reductions exceeding 60%.

The comparison demonstrates that while the Philip correction addresses specific physical distortions, it is limited by uncertainties in plate parameters. Conversely, the field calibration method provides a robust, practical solution for achieving high accuracy in long-term field measurements without requiring detailed knowledge of plate properties or soil physics.

# Pore systems and functions in structured soils- how far affect soil management and environmental impacts an unambiguous assignment?

**Prof. Dr. Rainer Horn**

*Instituter of Plant Nutrition and Soil Science, Christian Albrechts University, Kiel, Germany*

## ABSTRACT

Geogenic, pedogenic, and anthropogenic impacts affect soils concerning their chemical, physical and biological properties and functions and their rigidity or resilience and sustainability. Under energetic aspects (Fig.1) can we define the various affecting potentials for structure formation, their rigidity and the multitude of dependencies.

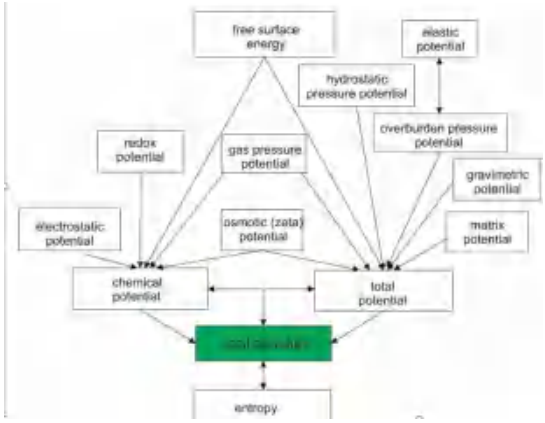

Fig.1: Energy concept influencing structure formation (slightly modified with courtesy of Zimmermann 2022)

It is furthermore well-known, that hydraulic, mechanical but also thermal processes (via osmotic, hydrophobic, surface tension and viscosity impacts) are all coupled and control on the macro- and microscale particle arrangements and aggregation as well as the accessibility of pores and their continuity including the often-available capillary barrier effects. The link between mechanical strength and accessibility of particle surfaces e.g. documents the dependency on aggregation but during shrinkage and swelling undergo the newly formed aggregates intense lateral compression and vertical shear as well as lateral displacement which all alter the pore accessibility as well as their filter and buffer capacity. Thus, the statement must be restricted only to the rigidity limits defined e.g. by precompression stress as the transition from recompression stress to the virgin compression load range (defined by mechanical processes) or the previous minimal water potential which defines the transition from the structural shrinkage to proportional shrinkage (hydraulic processes). If the aggregate-related strength “history as a site-specific memory” is exceeded by actual hydraulic ,thermal, mechanical or chemical, biological impacts, ), a new proportional shrinkage results in a contraction of the aggregated soil volume, followed by new crack formation and smaller but stronger aggregates that have, however, altered soil properties and functions. Consequently, also the often-predicted climate change impacts cause corresponding further more intense drying with stronger (more rigid) structure but consecutive changes in pore continuity and accessibility or availability of pore water etc. Fig. 2 shows the impacts of various stresses on changes in the saturated hydraulic conductivity and consequences on flux processes.

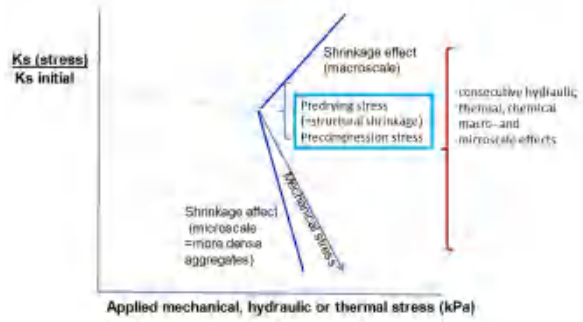

Fig. 2 Impact of stresses on changes in saturated hydraulic conductivity.

During the oral presentation will these interactions be discussed and consequences for modelling and predictability of processes as well as further research approaches analyzed.

# From Sedimentation to Laser Diffraction: A New Particle Size Distribution Classification Based on Soil Mechanical Properties

**Fomin Dmitriy [1*], Mitichkin Daniil [1]**

[1] *V.V. Dokuchaev soil Science Institute (Moscow, Russia)*

*fomin_ds@esoil.ru

**ABSTRACT**

*Background*: Modern studies demonstrate that determining soil texture classes according to Kachinsky (Russian classification) and USDA/FAO systems using particle size distribution data obtained by laser diffraction method leads to errors of 43% and 65%, respectively. This problem arises because existing classifications were developed based on sedimentation methods. Although laser diffraction and sedimentation methods correlate with each other, they are based on different physical principles, and conversion models between methods have proven inadequate.
*Objective*: To develop a new soil texture classification specifically designed for the laser diffraction method that ensures reliable interpretation of measurement data.

*Materials and Methods*: The new classification uses soil mechanical behavior (plasticity limit, liquid limit, plasticity index) and field-determined texture classes as References standards. A crowdsourced collection of 3,131 soil samples was assembled, varying in sampling location, texture class, organic carbon content, and soil type. All samples were analyzed for particle size distribution by laser diffraction, plasticity and liquid limits, and texture class was determined by field methods (cord-and-ring method/Kachinsky and ball-and-ribbon method/FAO/USDA). New boundaries for silt and sand fractions were established specifically for laser diffraction measurements. A machine learning model was developed to predict liquid and plasticity limits based on particle size distribution parameters obtained from laser diffraction.

*Results*: New fraction boundaries for silt and sand were determined for the laser diffraction method. Based on these boundaries, classification principles were developed and content ranges for silt and sand fractions were identified for both FAO/USDA and Russian (Kachinsky) classification systems. The ML model successfully predicts rheological properties from laser diffraction parameters, confirming the physical validity of the proposed classification system.

*Conclusion*: The newly developed classification eliminates the methodological gap between traditional sedimentation-based standards and modern laser diffraction instrumentation. It enables accurate interpretation of laser diffraction data within both international and national classification frameworks, promotes standardization of soil diagnostic studies, and can be integrated into digital soil mapping and precision agriculture protocols.

**ABSTRACT**

Bacterial biofilms play a crucial role in microbial survival during drought by modifying soil-water relations, yet their influence on water vapor transport in dry soils remains unexplored. We present the first systematic investigation of biofilm effects on soil water vapor sorption (SWVS) dynamics across a wide matric potential range (-400 MPa to -10 MPa). Using five soils of varying textures inoculated with Pseudomonas putida and Bacillus subtilis, we quantified SWVS isotherms while characterizing concomitant changes in surface and biofilm development. Key findings reveal that active biofilms persist in dry soils (water activity: aw < 0.9), fundamentally altering SWVS behavior through three mechanisms: (1) Enhanced water vapor adsorption capacity (10-49% increase across textures) due to extracellular polymeric substance (EPS) hydration; (2) Hysteresis reversal at critical aw values < 0.6, where biofilm-dominated adsorption exceeds mineral surface desorption; and (3) Displacement of mineral-water interactions by biofilm hydration. Mechanistic analysis demonstrates that EPS components dominate vapor sorption through high-density polar functional groups (-COOH and -OH) with strong water-binding affinity, polymer matrix swelling that physically obscures mineral surfaces, and competitive inhibition of cation hydration shells at particle interfaces. These findings establish biofilms as independent regulators of soil hydrology in dry conditions, with implications for microbial drought resilience strategies, soil water retention models in arid ecosystems, and biofilm-mediated contaminant transport. The study provides a framework to predict vapor-phase water redistribution in biofilm-colonized soils, filling a critical gap in the understanding of biological controls on soil hydraulic processes.

# Optimizing implementation strategies for efficient soil water evaporation measurements with multi-probe heat pulse sensors

**ABSTRACT**

A multi-probe heat pulse (HP) sensor measures in-depth variations of water evaporation rates ($E$) in subsurface soil layers. A multi-probe HP sensor requires an input source of heating power, a high-frequency data logging system, and computer software for data analysis, which may hinder its adoption for a wide use in field applications. This study aims to optimize the measurement configurations via systematic evaluations of vertical probe distributions, heater probe requirements, and thermal property sampling intervals. Field data obtained with an 11-probe HP sensor revealed that 87% of evaporation occurred within the 0-23 mm soil layer during drying cycles, requiring the use of only seven temperature probes and two heater probes ($RMSE$ < 0.02 mm $h^{-1}$ vs. full configuration). Thermal property measurement intervals could be extended from 4 to 8 hours when timed to capture critical daytime transitions in soil thermal conductivity, maintaining accuracy while reducing the data collection requirement by 38%. Soil thermal gradients accounted for > 90% of sensible heat flux values, it was essential to maintain millimeter-scale precision on the depth placement of the topmost probes. These quantified operational thresholds provide sensor manufacturers and field researchers with evidence-based design criteria that balance measurement integrity and system efficiency.

# Root-soil interface traits in modern and landrace barley genotypes differ in the lab but not the field

**Sean Graham[1,2*], Timothy S. George[2], Maria Marin[2], and Paul D. Hallett[1]**

[1] *University of Aberdeen (School of Biological Sciences, Aberdeen, UK)*

[2] *The James Hutton Institute (Ecological Sciences, Invergowrie, UK)*

*s.graham2.23@abdn.ac.uk

**ABSTRACT**

Having been domesticated 10,000 years ago, barley is one of the oldest cereal crops and the fourth most grown in the world. Historic landraces are reported to have adaptations to nutrient and water use efficiency, and possibly a greater capacity to modify rhizosphere physical structure through root-soil interface traits but it is unknown if these have been 'bred out' in modern cultivars. Within Scotland, the "Bere" barley landrace is a multipurpose crop with cultural importance and evidence of advantageous root-soil adaptations to micronutrient deficiency.

We investigated the genetic potential of early seeding Bere genotypes under controlled conditions and found that they had up to 32 % larger total and specific rhizosheath (g/cm) than an elite cultivar KWS Curtis ($p<0.001$) despite having similar root lengths. Subsequent field validation with KWS Curtis and the largest rhizosheath forming Bere genotype "Unst" was conducted in two different Scottish Cambisols during the 2025 growing season- the driest in 30 years.

The most profound effect of these suboptimal conditions was in the above ground portion of the plant: mature plants grown in sandy loam soil had 4 times greater yield and 1.7 times greater above ground biomass than plants grown in loam soil ($p< 0.001$) and showed no significant difference in fresh root or total rhizosheath mass. Additionally, the root architecture of field grown plants were highly branched and showed diversity in root diameter when compared with controlled grown plants. This is expected to influence specific rhizosheath to a greater extent than total rhizosheath which is currently being evaluated. In the field at seedling stage, the total rhizosheath was less than half the size as under controlled conditions. Additionally, rhizosheath size in the field varied considerably with time and was more difficult to collect when soil moisture approached the wilting point. Ongoing work is exploring the 3D pore structure of the rhizosheath in the field using X-Ray CT imaging.

In spring 2026, the field study will be repeated and coupled with more in-depth measurements of root-soil interface properties to gain further understanding of Bere rhizosheath formation under varying field conditions.

# Seasonal dynamics of soil structure and water retention of field soils with different long-term amendment rates of slurry and compost: measurements and modelling

**Utibe E. Utin[a,b,d], Josie Geris[b], Jo Smith[a], Kenneth Loades[c], David Boldrin[c] and Paul D. Hallett[a]**

[d]*Department of Soil Science and Land Resources Management, University of Uyo, Uyo, Nigeria*

**ABSTRACT**

Over times as short as hours after tillage, soil structure and water retention characteristics can vary markedly, with longer-term impacts dependent on the form and quantity of organic inputs. While many studies have observed seasonal soil structure shifts due to organic amendments and cultivation, little data exists on water retention characteristics due to the time and expense required. In this study we apply a new inferred Assouline model that can infer soil water retention characteristics at different time points based only on simpler measurements of saturated water content, bulk density and macroporosity. We apply it to a field experiment exploring long-term field applications of 0, 10, 20 and 40 Mg ha$^{-1}$ slurry and 0, 35, 100 and 200 Mg ha$^{-1}$ compost (by fresh weight). Measurements were taken at post-planting and post-harvest across two years. Increasing amendment rates raised soil organic carbon (SOC) by 15 g kg$^{-1}$ in the highest slurry treatment and by up to 47 g kg$^{-1}$ in the highest compost treatment compared with the control. Consequently, bulk density significantly decreased from 1.15 Mg m$^{-3}$ in the control to 0.96 Mg m$^{-3}$ in soils treated with 200 Mg ha$^{-1}$ compost, while saturated water content followed the opposite trend. The form rather than the amount of SOC affected total porosity, which was significantly greater ($p \leq 0.05$) in compost-treated soils than in slurry-treated soils in both seasons, when the organic amendments were assessed at equivalent SOC content. There were variable effects of amendment type and time on soil structural and hydrological properties, but crop growth over the season helped regenerate soil structure and add new carbon, particularly in compost-treated soils, where microporosity and saturated water content increased post-harvest. From water retention characteristics assessed with the Assouline model, the scaling parameter related to drainage decreased from post-tillage (mean of 25 kPa for both amendments) to post-harvest (18 and 16 kPa in slurry- and compost-treated soils, respectively). Soil organic carbon also regulated drainage at more negative matric potentials, as reflected by lower exponential decline parameters at post-harvest (0.32-0.35) compared with post-planting (0.37-0.40). The scaling and exponential parameters were similar across treatments, suggesting a stronger influence of texture and soil management than of SOC content. Interaction effects between season and compost rate altered saturated water content and permanent wilting point, with decreases at post-tillage but increases at post-harvest. The new inferred Assouline model performed well, with 86 % of estimated soil water retention curves showing RMSE ≤ 0.05 m$^3$ m$^{-3}$ and an average $R^2$ of 0.96. Overall, maintaining high SOC through long-term organic amendments enhances pore stability, improves water retention, and supports soil health and productivity.

# Modelling the relationship between naturally occurring radionuclides and grain size of sediment of various river basins, South Africa

**J. Bezuidenhout**[1*]

[1] *Stellenbosch University*

*jb@sun.ac.za

**ABSTRACT**

This study examines the relationship between sediment grain size and naturally occurring radionuclide concentrations ($^{40}$K, $^{238}$U, $^{232}$Th) in the Helskloof Basin, South Africa. Sediment samples from the Klein Helskloof Valley were sieved into grain size fractions and analyzed by gamma spectroscopy using a 3×3 NaI(Tl) detector. Results show that $^{232}$Th concentrations consistently exceed $^{238}$U, while $^{40}$K correlates strongly with grain size and lithology, particularly in granodioritic areas rich in potassium-bearing minerals. Fitted activity–grain size relationships revealed a consistent minimum radionuclide activity between 612–678 µm (coarse sand), reflecting the dominance of low-radioactivity minerals such as quartz and feldspar. Similar studies in the Mkomazi and Tugela rivers, which differ markedly in lithology and climatic conditions, have shown that both geology and climate influence the relationship between grain size and radionuclide concentrations. These findings confirm that radionuclide distribution is controlled by lithology, climate, and sedimentary sorting, demonstrating the usefulness of natural radionuclides as tracers of sediment provenance and depositional processes.

# Construction of the Integrated Soil Database for Hydrological Modeling in Brazil

**Ottoni Marques Moura de Leon[1], Danielle Bressiani[2], Luis Fernando da Silva Martinez[3], Raghavan Srinivasan[4], and Luís Carlos Timm[5*]**

**ABSTRACT**

Hydrological modeling is an essential tool to support decision-making, with wide application in soil management and conservation studies, water resource management, and environmental impact assessment. Among the most widely used models is SWAT (Soil & Water Assessment Tool), which requires soil parameters such as saturated hydraulic conductivity, textural fractions, density, and depth to simulate soil-water interactions. For developing countries, the scarcity of reliable and adequately organized input data increases the uncertainties associated with hydrological simulations. Currently, there are three main alternatives for obtaining soil data for models: global databases, which are comprehensive but have low resolution; observed data, which are accurate but expensive and time-consuming; and open access databases, which balance quality and availability. This last option requires estimating missing data and organizing them into the model format using pedotransfer functions (PTFs). Processing and formatting demand time and technical knowledge of soils. Considering the demand from the modeling community, this study aimed to develop an Integrated Soil Database for Hydrological Modeling in Brazil, with reliable and open information compatible with the SWAT and SWAT+ models. To achieve this objective, the methodology consisted of: I - Defining the parameters and organizing the input data necessary for the SWAT model. II - Establishing a minimum set of attributes that each soil profile should contain to allow the estimation of other parameters using Profile Transfer Functions (PTFs). III - Obtaining comprehensive and reliable soil databases. For the current version of the database, we used three main sources: the Brazilian Hydrophysical Soil Database - HYBRAS, the Brazilian Free Soil Data Repository - FEBR, and the Soil Database of the Brazilian Agricultural Research Corporation (EMBRAPA). IV - Standardization, concatenation, and cleaning of data. V - Estimation of missing parameters through the application of PReferences Transfer Functions (PTFs) chosen based on the availability and suitability of predictors for Brazilian soils. This process estimated the hydraulic conductivity in saturated soil, soil density, available water content, USLE-K factor, and albedo. As a result, the Integrated Soil Database for Hydrological Modeling in Brazil was generated, containing 7,944 soil profiles distributed throughout the country. The database includes the parameters required by the models, in a ready-to-use format. The resulting database expands the potential and reduces the time and effort required for the application of the models in Brazil.

**ABSTRACT**

The gap between earth system or climate model simulations and observations is still a topic of scientific and political concern. The latest phase of the Coupled Model Intercomparison Project (CMIP) is still showing overestimations in near-surface air temperature among other parameters, despite various model structural improvements and numerical advances. Great efforts have been made to increase model skill, yet few studies considered the heat transfer within soil and at the land-atmosphere interface, which are dominated by soil thermal conductivity (STC) parameterization schemes (PS). By incorporating the commonly used STC-PS of various mainstream land surface models (LSMs) of earth system and climate models into the Community Earth System Model (CESM) and comparing with European Center Reanalysis version 5 (ERA5) and FLUXNET data, we found that the role of STC-PS in earth system model has been underestimated. The results unveil that STC-PS alone can lead to errors in global mean absolute bias (MAB) of shallow soil temperature of 2.1 °C with a 5~95% range of 1.75~3.26 °C. These errors propagate via the land-atmosphere interactions and feedbacks in earth system models, leading to MAB for near-surface air temperature of 1.67 °C with a 5~95% range of 1.53~2.07, and for sensible and latent heat flux of 9.8 W $m^{-2}$ with a 5~95% range of 7.8~12.4 W $m^{-2}$. Therefore, uncertainties arisen from STC-PS to a considerable extent explain the overestimated global mean temperatures and affect the decision-making processes concerning the global temperature rise targets. Hence, there is an urgent need to improve the neglected STC-PS to better understand our earth system, how it is affected by climate change and to guide our decisions on the best climate change mitigation strategies.

## ABSTRACT

Saturated soil hydraulic conductivity (Ksat) is a key factor in hydrological management projects and its variability along the landscape hinders its correct use in the formulation of such projects. Ksat varies under different climatic and hydrological conditions at spatial scales as reported in several studies. However, the applicability of the state-space approach to predict saturated soil hydraulic conductivity to other soils that do not belong to the data pool used to generate them remains a challenging aspect with regard to identifying supportive co-variates and suitable spatial models. The objectives of this study were to (i) describe the spatial continuum of Ksat across a 25 km-spatial transect established in the Pelotas River Watershed (BHAP) (Fig. 1), Southern Brazil, through co-regionalization with an autoregressive state-space model, (ii) evaluate its applicability to predict Ksat data along a 15 km-spatial transect established in the Fragata River Watershed (BHAF) as well as to predict Ksat data on a sampling grid of 106 sampling points spaced 50 m by 75 m established in a headwater sub-basin (BHSE) of the Pelotas River Watershed. One hundred soil sampling points were distributed along the 25 km-spatial transect at equal distances (250 m) where Ksat, Clay and Sand contents and soil bulk density (BD) were determined for the 0-20 cm layer at each point. The same data sets were determined in the BHAF and BHSE watersheds. Mean, standard deviation, maximum and minimum values were calculated for each data set. A lognormal transformation was applied to Ksat data set since that did not show normality. The Spearman rank correlation coefficient, autocorrelation and crosscorrelation functions were calculated to evaluate the spatial relationships between Ksat and the other three variables. A state-space model was run to assess the spatial relationships between Ksat and Clay and Sand and BD data sets in the 25 km-spatial transect where 92.37 % of the local variations of Ksat were explained by those of Clay, Sand and BD data sets. The variance parity test of Levene was applied between each data set of Ksat, Clay and Sand fractions in order to verify the homogeneity of variance. Results show that the BHAP-state-space model captured the local variations of Ksat in the BHAF and in the BHSE showing its potential to predict Ksat of basins with scarce data and similar soil and land-use conditions.

## ABSTRACT

No-till management is widely practiced in South Dakota, but cropping systems are increasingly dominated by simple corn (*Zea mays* L.)-soybean [*Glycine max* L. (*Merr*.)] rotations, reducing crop diversity. We conducted this study to determine how declining crop diversity affects soil porosity, hydro-physical properties, and carbon storage in a long-term no-till field experiment with two crop rotations initiated in 1991. The experiment used a split-plot design in which a four-year corn–soybean–oat (*Avena sativa* L.)-rye (*Secale cereale* L.) rotation and a two-year corn–soybean rotation formed the main plots. Cover crop (CC) and no cover crop (NCC) treatments were implemented as split plots in 2013. Intact soil cores were collected at 10-cm intervals from 0 to 40 cm in 2022 and analyzed using X-ray computed tomography to quantify macropore characteristics, and hydro-physical properties were measured in the laboratory. The diversified four-year rotation increased macropore counts and density by 27% and 28%, respectively, compared with the two-year rotation at 0-10 cm. However, cover cropping exerted a stronger influence, increasing macroporosity and macropore counts by at least 30% and total porosity by 9% compared with NCC at 0-10 cm depth. In addition, CC treatments elevated soil organic carbon and total nitrogen concentrations at 0-10 cm and enhanced saturated hydraulic conductivity by 42-75% from 0 to 30 cm depth. These findings indicate that cover crops play a larger role than rotation diversity in improving soil porosity, carbon storage, and hydraulic conductivity within this long-term no-till field. Integrating cover crops into no-till management, therefore, represents a key strategy for building soil function and supporting more resilient cropping systems in South Dakota.

## ABSTRACT

Dry-wet cycles (DWCs), defined as alternating periods of dry and wet conditions in the soil, are predicted to occur more frequently worldwide due to the current change in global climate. These fluctuations in soil moisture conditions can affect soil structure and hydraulic properties, which can have a direct effect on biogeochemical processes such as mineralization. However, limited studies have examined how changes in soil physical and hydraulic properties during DWCs influence soil nutrient mineralization. The objective of this laboratory study was to characterize the impact of DWCs on nitrogen (N) and phosphorus (P) mineralization from two soils (a silty loam and a clay loam) amended with cattle manure. We also explored correlations between mineralization and field capacity (FC), permanent wilting point (PWP) and available water content (AWC) measured from a separate experiment investigating the impacts of DWCs on water retention parameters. Soils were mixed with cattle manure at a rate of 150 kg N $ha^{-1}$, adjusted to 60% of FC, and incubated at 30°C under three DWCs treatments (4, 8, and 12 DWCs). Each DWC consisted of a 2-day dry period followed by a 1-day wet period. A control treatment, not subjected to DWCs, was included for comparison. The experiment was arranged in a completely randomized design with all treatments replicated four times. After 36 days of DWCs, samples were maintained at 60% of FC for an additional 28 days, resulting in a total incubation period of 64 days. At the end of the incubation, available N (2 M KCl extractable $NH_4^+$ + $NO_3^-$) and P (Bray) were determined, and net N mineralization ($N_{min}$) and net P mineralization ($P_{min}$) were calculated. Results showed a significant decrease in $N_{min}$ only after 12 DWCs (45.31 mg $kg^{-1}$) relative to the control (76.98 mg $kg^{-1}$) in the clay loam but not in the silty loam. Correlation analysis revealed a strong negative relationship between $N_{min}$ and water retention at FC ($r$ = -0.90, $p < 0.0001$), PWP ($r$ = -0.82, p = 0.0001) and AWC ($r$ = -0.81, p = 0.0001) in the clay loam. In the silty loam, the relationship between $N_{min}$ and water retention parameters was weak and insignificant. Net P mineralization was not significantly affected by DWCs but differed significantly between the two soils, with both soils showing negative values. $P_{min}$ in the silty loam (-27.06 mg $kg^{-1}$) was significantly lower than clay loam (-19.50 mg $kg^{-1}$). In the clay loam, $P_{min}$ showed no significant correlation with water retention parameters, whereas in the silty loam, $P_{min}$ was positively correlated with AWC. Our results suggest that the link between soil water retention parameters and N and P mineralization under DWCs is soil-dependent. This study provides insights into how shifts in hydraulic properties driven by DWCs can influence nutrient cycling under a changing climate.

# Biochar Effects on Soil Hydrophysical and Chemical Properties: Texture and Particle Size Matter

**L. Reim[1,2,3,*], B. Hafner[1], M. Zarebanadkouki[1]**

[1]*Soil Biophysics and Environmental Systems, School of Life Sciences, Technical University of Munich, Germany.*

*laurin.*reim*@mitigate.eco

**ABSTRACT**

Climate change poses critical challenges to soil and crop systems, particularly through increased drought frequency. Biochar (BC), a carbon-rich byproduct of biomass pyrolysis, has been proposed as a nature-based solution to enhance soil climate resilience. However, the variability in BC effects across different soil types complicates the predictability of its potential impacts and economic viability. This study systematically investigates the effects of BC on the hydrophysical and chemical properties of soils with contrasting textures – sand (S), silt loam (SiL), and clay (C).

We selected hardwood-derived BC (pyrolyzed at 550 °C), sieved it into two particle size fractions (63–200 µm and <63 µm), and mixed them to produce three differently textured BC types (1/4, 1/1, 4/1) with particle sizes ranging from 2 to 200 µm. These BCs were mixed with the soils at application rates (ARs) of 0%, 1%, and 5% (w/w), resulting in 21 unique soil-biochar mixtures (SBMs) including controls. Key soil properties – including pH, electrical conductivity (EC), bulk density (BD), porosity (Φ), unsaturated and saturated hydraulic conductivity ($K_h$ and $K_S$), water retention characteristics (θ), and plant-available water (AW) – were quantified, following a 16-weeks incubation with an initial 15% (w/w) water addition at 18 °C and a subsequent air drying <45 °C.

Results revealed significantly improved AW and K in sand, enhanced KS, BD, and total porosity in silt loam, and moderately altered water availability and KS in clay. The effects were strongly influenced by both soil texture and BC particle size, with fine BCs at higher ARs generally producing the most pronounced effects. A consistent pattern in water retention and flow characteristics was observed in relation to the particle size distribution (PSD) of both soil and BC in the SBMs. Additionally, AR and particle sizes mattered most in orchestrating pore reconfigurations that increased mesoporosity in coarse and fine-textured soils. Moreover, pH increased substantially in BC-amended sand treatments, while changes in silt loam and clay were moderate to minimal, respectively.

This study underscores the necessity of texture-specific BC application strategies and supports BC's role as a viable tool for enhancing soil water regulation and resilience in agricultural systems. Further experiments with exhaustive input data will facilitate accurate predictability of soil-biochar interaction, improving our preparedness for soil-related climate change risks.

**ABSTRACT**

The Vertisol (Shajiang black soil) in China is mainly distributed in the southern part of the Huanghuai plain with an area of 4 × 106 hm$^2$. The poor soil physical properties during shrinkage-swelling greatly limit crop growth. This study was based on a long-term field experiment including no-tillage (NT), rotary tillage (RT), subsoiling (SS) and deep ploughing (DP). With combined commercial soil moisture and thermal property sensors, the dynamics of bulk density (ρb) in 0-10 cm and 10-20 cm layers under different tillage treatments were monitoring in situ. The ρb dynamics in the 0-20 cm in the NT and the 10-20 cm layer in RT treatment were mainly caused by shrink-swelling. However, the ρb dynamics in the 0-20 cm in the DP and the 0-10 cm layer in RT treatment were predominantly determined by soil subsidence first and then shrink-swelling. A two-stage equation for the relation between ρb and soil moisture was proposed. The soil subsidence and shrink-swelling stages accounted for 17.0%-24.0% and 19.0%-32.5% of the ρb variation over the year, respectively. The dynamic of the least limiting water range (LLWR) was then derived from the established pedotransfer functions and the ρb dynamic. Thus, the relationship between the waterlogging stress time and the antecedent soil water storage and rainfall was established. The threshold of rainfall leading to the waterlogging stress of more than 3 days in the 0-10 cm and 10-20 cm soil layer were 83.7-127.2 mm and 54.2-86.6 mm respectively. When the rainfall stress events exceed 2 times, the maize yield will decrease by more than 50%. Compared with the NT and RT treatments (83.7-93.2 mm and 54.2-64.7 mm), the soil under the DP treatment held more rainfall (127.2mm and 86.6mm), reducing the risk of waterlogging stress. This study provides new understanding the relation between dynamic of soil structure and waterlogging stress.

# Soil structure versus soil life: Microbial resilience to compaction in contrasting soil types

**M. Timofeeva[1*], A. Yudina[2]**

[1]*Department of Soil Physics and Hydrology, V. V. Dokuchaev Soil Science Institute, Moscow, Russia*

[2]*Department of Soil Physics and Hydrology, V. V. Dokuchaev Soil Science Institute, Moscow, Russia*

* timofeeva_mv@esoil.ru

**ABSTRACT**

Soil structure, defined as *"spatial arrangement of solids and pores"* is a key regulator of processes responsible for critical soil functions. Pores of different sizes provide distinct habitats for microorganisms, influencing their activity. Soil compaction alters pore architecture, yet its effects on microbial communities remain poorly understood, particularly across soil types. We hypothesized that compaction-induced changes in pore structure would differentially affect microbial activity depending on soil organic carbon content and texture.

We conducted a microcosm experiment using two soils with contrasting properties. Hortic Chernozem (Aric), (silty clay loam, total organic carbon (TOC) is 3.82 ± 0.02 %) from the Kursk and Stagnic Retisol (Cutanic) (sandy loam, total organic C is 1.93±0.01 %) from Tver regions in Russia. Soil microcosms were assembled according to the average macroaggregate composition with and without plant residues (*Zea mays L.*) were then compacted under uniaxial compression up to effective bulk densities (BDeff) of 1.3; 1.4; 1.5; 1.7 g.cm-3. Microcosms of Chernozem and Retisol incubated for 22˚C during 70 and 245 days, respectively. Moisture content was maintained filling the soil pore space within the range 40–60%. During incubation soil, sampling took place for biological activity determination. Soil structure in microcosms was evaluated using X-ray computed tomography.

Total soil porosity reduced by 6-fold with an increase in BDeff from 1.3 to 1.7 g.cm-3 in Chernozem and by 4-fold in Retisol. Despite this structural deformation under soil compaction, the differences in microbiological activity were poorly pronounced. The microorganism's response manifested in just soil microbial respiration decrease and partly in extracellular enzyme activity (EEA) fall. We hypothesized that this phenomenon occurred due to the dominance of physical effects over biological responses in short term. With a 10% decrease in porosity the gas diffusion decreases up to 10 times. At the same time micropores (< 30 μm) volume, where a large proportion of microorganisms reside – remains unchanged or increases under external influences. Probably, labile components were consumed within the first several days while more stable fractions remain inaccessible. That is why the microbiological properties at 70 days were the same in Chernozem.

Our findings suggest that soil organic carbon content and texture mediate microbial resilience to compaction, with implications for predicting biological responses to agricultural traffic in different soil types. Carbon-rich loamy soils have a diverse and abundant microbial community and can provide a high buffering capacity to external influences while Retisol with a low TOC and a high content of sand cannot sustain this, particularly over extended periods.

# Soil moisture, irrigation efficiency, and soil strength interactions under centre pivot irrigation

**Ana Carolina De Mattos EAvila[1*], Caroline Mohammed[1], and Marcus Hardie[1]**

[1]*Tasmanian Institute ofAgriculture, University ofTasmania, Hobart, Australia*

*ana.avila@utas.edu.au

**ABSTRACT**

Water security is increasingly recognized as a critical challenge for agriculture, particularly as irrigation expands into soils with limited infiltration and high susceptibility to waterlogging. Understanding how water moves through soil under centre pivot irrigation is essential for improving water use efficiency and ensuring sustainable food production. Efficient irrigation requires not only uniform water application but also effective soil infiltration and storage. This study integrates soil moisture sensing, application uniformity, runoff measurements, and soil penetration resistance to evaluate water movement and soil physical constraints under centre pivot irrigation in Tasmanian soils. Application uniformity assessed with catch cans was high (CU = 95%, DU = 92%), indicating that the system distributes water evenly. However, soil moisture data from Sentek Drill & Drop sensors reveal that most of the applied water remains confined to the upper 0–10 cm, with minimal increase at 15–30 cm and no detectable change below 45 cm. Runoff measurements ranged from 0 to 23 mm, with an average of 5.3 mm, confirming that a substantial portion of the applied water did not infiltrate. Dye tracer and wetting-footprint observations further showed lateral redistribution and surface flow even on gentle slopes. Soil strength measured with a Rimik CP-300 penetrometer frequently exceeded 2 MPa in the upper 15– 20 cm, the threshold commonly associated with restricted root growth and reduced infiltration. Areas with higher cone index coincided with shallower infiltration, faster surface saturation, and greater runoff, indicating that compaction is a key physical constraint limiting irrigation efficiency despite excellent application uniformity. Together, these measurements demonstrate the importance of evaluating not only irrigation system design but also soil physical conditions that control water entry, storage, and movement. This integrated approach provides a practical diagnostic tool for improving irrigation scheduling, soil management, and water productivity in pivot-irrigated systems.

**ABSTRACT**

Soil compaction from machinery traffic degrades soil structure, limits water movement, and reduces agricultural productivity. This study evaluated how tractor tire inflation pressure, soil texture, and long-term management history influence void morphology and porosity using X-ray computed tomography (CT). Well-managed soils shaped by reduced tillage and cover cropping were compared with poorly-managed soils exposed to intensive tillage and frequent traffic. Clay-loam and sandy-loam soils were subjected to low tire inflation pressure traffic, high tire inflation pressure traffic, and non-traffic control treatments. Well-managed clay-loam soils showed greater porosity and more fine voids, whereas poorly-managed clay-loam soils exhibited reduced porosity and stronger sensitivity to compaction, particularly under high inflation pressure. In sandy-loam soils, poorly-managed soils had greater porosity than well-managed soils and showed little change regardless of tire inflation pressure traffic treatments. Horizontally oriented voids dominated across all treatments, while vertical and inclined voids varied with management and texture. Compaction effects were most pronounced at 15 cm depth, with limited structural change at 30 cm. X-ray CT detected subtle compaction-induced changes in pore size and void orientation that bulk density could not capture. Although tire inflation pressure significantly affected clay-loam structure, management history more consistently shaped void morphology and porosity across both soil types, highlighting the importance of long-term conservation practices in mitigating compaction.

**ABSTRACT**

Microbial interactions are in the core of evolutionary and ecological processes in soil and other environments, including horizontal gene transfer mediated by conjugative pili,[1] quorum sensing,[2] and chemical signaling that shapes social behaviors.[3] Although studies have reported that heterogeneous environments often induces population segregation into distinct microhabitats for long-term coexistence,[4] structured environments such as soils commonly generate localized polymicrobial interaction hotspots.[5] These hotspots promote the spatial organization of bacterial communities and contribute to soil biogeochemical processes.[6] However, our understanding of the environmental factors controlling these interactions remains limited. Under most conditions, natural soils are unsaturated, where fragmented aqueous habitats undergo frequent dry–wet cycle hydration processes,[7] significantly influencing passive bacterial dispersal and subsequent microbial interactions based on direct contact and molecular exchange.[8] Here, we show that small-scale hydrodynamic processes mediated by dry–wet cycle can passively drive microbial dispersal within populations, promoting the exchange genetic materials. Through experiments, we demonstrate that hydration-driven hydrodynamics can balance fitness differences between competing populations by restricting the dispersal of motile bacteria and facilitating the expansion of non-motile bacteria. These processes passively drive two previously segregated populations remix at the expanding front, resulting in spatial hotspots of conjugation. This study highlights the key role of microscale hydrodynamics in mediating bacterial interactions and genetic exchange, emphasizing the ecological impact of dynamic hydration on microbial interactions within structured environments.

# Long-term organic fertilizer substitution alleviates the surface soil compaction of a Vertisol by improving soil structure

**Liman. AO[1*], Ziye Cheng[1], Linchuan Zhan[2], Lebin Guo[1], Keke Hua[2], Daozhong Wang[2], Zhaoxia Li[1]**

**ABSTRACT**

Inappropriate fertilization management has emerged as a major driver of soil compaction in arable systems, suppressing crop growth and jeopardizing the long-term sustainability of agriculture. However, the mechanisms underlying plough-layer compaction induced by fertilization remain unclear, and the extent to which different substitution ratios of organic fertilizer alleviate soil compaction is still insufficiently understood. Here, we examined fertilization regimes established in 2012 to assess the long-term impacts of organic fertilizer substitution (NPK, 20%, 60% and 100%OM) on the physical properties and compaction characteristics of the 0-15 cm surface horizon in the Vertisol. Relative to the unfertilized control (CK), exclusive organic fertilization (100% OM) significantly increased cation exchange capacity, soil organic carbon (SOC), and glomalin-related soil protein (GRSP), and improving aggregate stability and promoting the transition of 0.25-2 mm aggregates into macroaggregates (>2 mm). By contrast, sole mineral fertilization (NPK) elevated SOC but reduced CEC, GRSP, and macroaggregate content, while markedly lowering soil pH. Pore-structure analysis demonstrated that compaction in Vertisol is not restricted to superficial crust within the 0-20 mm layer but represents a structural transformation across the surface soil layer, with the uppermost horizon being most severely affected. Long-term, high organic fertilizer substitution enhanced total porosity, 100%OM showing 2.84-fold higher porosity than CK. Rainfall markedly reduced porosity in 100%OM by ~119.17%, whereas sustained low organic fertilizer substitution and NPK decreased it and induced conspicuous cracking after rainfall-drying cycles, reflecting unstable soil structure. SOC, CEC, and GRSP emerged as key regulators of compaction, exhibiting strong correlations with aggregate stability. Although excessive organic inputs may lead to localized salt accumulation, the incorporation of crop residues seems to alleviate this and improved structural resilience. Overall, our findings highlight the contrasting roles of different proportions organic fertilizer substitution in shaping soil structural dynamics, providing new insights into the mechanisms of plough-layer compaction and strategies for sustainable Vertisol management.

**ABSTRACT**

Soil saturated hydraulic conductivity (Ks), as a fundamental property governing the behavior of water in the soil environment, is important to agriculture, environmental quality, water resources management, and engineering practices. However, the intricate interplay between Ks and environmental factors leads to substantial variability, making direct measurement costly and challenging. To provide a cost-effective indirect method with regard to Ks estimation, we proposed a portable modeling framework combing partial least squares structural equation modeling and artificial neural network (PLS-SEM-ANN). The framework was applied to a mountainous watershed characterized by humid climate, steep topography, and diverse land use. This approach demonstrated that the PLS-SEM-ANN was efficient in Ks modeling with a prediction accuracy of more than 80% ($R^2$ of 0.989 and 0.862 for model training and validation), which is comparable to that of the conventional artificial neural network ($R^2$ of 0.993 and 0.843 for model training and validation). According to structural equation modeling, land use significantly affected Ks through direct ($\beta$=0.237, $p<0.05$) and indirect ($\beta$=0.263, $p<0.05$) pathways, and soil properties, especially soil particle composition, were the most direct factor affecting Ks ($\beta$=0.410, $p<0.01$), while topography had a lesser effect on Ks ($\beta$=-0.023, $p> 0.05$). However, Shapley additive explanations (SHAP) analyses of PLS-SEM-ANN revealed significant nonlinear effects of topography on Ks, especially slope (SHAP mean absolute value = 0.92). Moreover, threshold testing showed that there was an abrupt change in the slope-Ks relationship at approximately 21°, with the effect of slope on Ks turning from positive to negative. This study provides an approach with explainable and transparent modeling results for Ks.

# Straw incorporation depth drives microbial carbon sequestration by remodeling physical habitat in Mollisols

**Ming Gao[1], Chunzhu Liu[1],Wenxiu Zou[1*]**

[1] *Northeast Institute of Geography and Agroecology, Chinese Academy of Sciences, Harbin 150081, China*

*E-mail Address of Presenting Author: zouwenxiu@iga.ac.cn

**ABSTRACT**

***Background*** The retention of soil organic carbon (SOC) is inextricably linked to microbial metabolic activities within their physical microenvironments. However, the "physical-biological" coupling mechanism by which deep straw incorporation—a key management practice—drives carbon sequestration remains poorly understood.

***Methods*** Based on a 15-year field experiment in Mollisols, we compared three treatments: conventional tillage (CT), shallow straw incorporation (SS, 0–20 cm), and deep straw incorporation (DS, 0–35 cm).

***Results*** Result showed that SIT effectively constructed a favorable physical habitat in the subsoil (20–35 cm), significantly increasing macropore (>75 μm) volume by **42.4%** and enhancing pore connectivity by **2.5 times**. This structural improvement facilitated water infiltration; stable water isotope analysis ($\delta^2H$, $\delta^{18}O$) revealed a **16.3%** increase in the contribution of "new water" in the subsoil, while the mean residence time (MRT) of water was prolonged by **24%** compared to SS. By remodeling the physical environment, DS alleviated microbial resource limitations, enriched microbial taxa, and elevated their genetic potential for decomposing complex polymers (e.g., cellulose/lignin-degrading CAZyme genes increased by **45.8%**). Consequently, enhanced microbial activity promoted the accumulation of microbial-derived carbon, raising the contribution of fungal necromass to mineral-associated organic carbon (MAOM) to **58.2%**, and increasing total subsoil MAOM stocks by **30.5%** compared to CT.

***Conclusion*** This study confirms that deep straw incorporation promotes soil carbon sequestration potential by remodeling the physical habitat to drive a fungal-mediated microbial carbon pump, providing a mechanistic basis for optimizing straw management to enhance soil carbon storage.

# Estimation of soil water retention curves by combining thermal conductivity and electrical conductivity curves

**ABSTRACT**

Soil water retention curve (SWRC), which describes the relationship between soil pressure head (*h*) and water content (θ), is fundamental for modeling water flow and solute transport in vadose zone hydrology. However, accurate estimation of SWRC across the entire θ range remains a challenge due to limitations in direct measurement methods and the constrained applicability of existing indirect models. Previous studies have independently explored the use of soil thermal conductivity (λ) or electrical conductivity (σ) for SWRC estimation, but these approaches are typically effective only within limited θ ranges. We hypothesized that λ and σ provide complementary information for estimating the soil water retention curve due to different pore-water regimes. Our investigation, conducted across a range of soil textural classes, confirmed that λ is the dominant parameter in dry to moderately wet conditions, owing to the formation of solid-liquid thermal pathways. In contrast, σ becomes more effective in wet conditions due to a sharp increase in ionic conduction through continuous liquid pathways.

Leveraging these complementary contributions and analogous conduction mechanisms, we developed a novel, two-segment pedotransfer function to estimate the SWRC across the full θ range using both λ and σ curves. Validation against independent laboratory datasets with simultaneous measurements of SWRC, λ, and σ demonstrated that the integrated model significantly improves estimation accuracy, reducing the root mean square error (RMSE) by over 20% compared to single-property models. This approach provides a more reliable and practical method for characterizing soil hydraulic properties across diverse moisture conditions.

**ABSTRACT**

Soil hydraulic properties, such as the soil–water retention curve (SWRC), play a crucial role in simulating water transport within the vadose zone. They can be directly measured in the laboratory or field, or indirectly predicted by using Pedotransfer Functions (PTFs). It has been advocated that accounting for soil structure could marginally improve the prediction accuracy of PTFs in its wet range. This study evaluated whether integrating easy-to-determine soil structure variables, specifically a visual soil assessment score (Sq from CoreVESS) and penetration resistance (PR), could improve PTF accuracy. We analyzed 252 soil horizons from 42 crop fields exhibiting varying soil structural degradation. We compared classical regression and machine learning (e.g. k-Nearest Neighbors, KNN) approaches to develop both point and parametric (Van Genuchten) PTFs. To evaluate the effect of data grouping, the dataset was split in two based on structure and on texture. Overall, KNN-PTFs achieved the best performance showing the highest $R^2$ and lowest RMSE values. Moreover, the point PTFs showed much better and more stable predictive ability than parametric PTFs. The inclusion of PR as an additional predictor variable slightly improved the prediction performance in the wet range of the SWRC. Interestingly, Sq proved beneficial when substituted for bulk density but not when used in addition to it. Grouping data based on texture and structure improved the prediction accuracy of the PTFs, but not in KNN-PTFs.

Extending these point-scale findings, our current research focuses on upscaling assessment to a field scale. We aim to outperform current methods by integrating traditional soil sampling with semi-quantitative visual assessment techniques and non-invasive geophysical prospecting. More specifically, we explore the potential of methods such as electromagnetic induction, ground penetrating radar, seismic methods and electrical resistivity tomography to better understand it at different depths. In this way, complex soil hydraulic properties can be characterized at field scale using practical, non-invasive in-situ measurements.

# Hydrodynamic Shear Stress Regulates P. aeruginosa Attachment via Motility Organelles

**Chen Song[1*], Zheng Han[1,2], and Gang Wang[1]**

[1] *College of Land Science and Technology, China Agricultural University, Beijing, China*

[2] *College of Resources & Environment, Huazhong Agricultural University, Wuhan, China*

*sc2022@cau.edu.cn

**ABSTRACT**

Soil biofilms participate in the biogeochemical cycles of most elements. While the formation of mature biofilms is well documented, the impact of hydrodynamic conditions, particularly fluid shear stress, on the early stages of biofilm formation (attachment and colonization) remains largely underexplored. This study investigated the micro-mechanism of *Pseudomonas aeruginosa* (PAO1) biofilm formation under shear stress from a biophysical perspective.

Using a flow culture system established with microfluidic chips and injection pumps, we examined the attachment behaviors of Ancestral PAO1 and its two motility mutants: flagella-deficient (Δ*fliC*) and type IV pili-deficient (Δ*pilA*). Biofilm development was monitored using Confocal Laser Scanning Microscopy (CLSM) and analyzed alongside theoretical modeling.

The results demonstrated distinct responses to varying shear stresses. At a low shear stress of 0.25 dyn/cm², the presence of flagella significantly influenced bacterial distribution and quantity. Both Ancestral PAO1 and Δ*pilA* strains developed complex "mushroom-shaped" biofilm structures, whereas the Δ*fliC* mutant did not, indicating that flagella play a critical role in the architectural development of biofilms.

Under a moderate shear stress of 0.6 dyn/cm², the attachment ability was ranked as: Δ*pilA* > Δ*fliC* > Ancestral PAO1. While type IV pili facilitate initial surface anchoring, their associated twitching motility, combined with flagellar swimming enhanced near-surface motility, which was unfavorable for stable attachment under these flow conditions. Furthermore, under shear stress, PAO1 strains possessing type IV pili exhibited a tendency to crawl along the flow direction.

At high shear stress of 6 dyn/cm², physical forces dominated over biological mechanisms. The increased drag force prevented cellular aggregation and 3D structure formation, resulting in a dispersed, monolayer distribution for all strains.

In conclusion, fluid shear stress significantly dictates the spatial structure and attachment dynamics of *P. aeruginosa* biofilms. The interplay between shear forces and bacterial motility organelles (flagella and type IV pili) is a key determinant in the early-stage colonization of surfaces.

# Root-mediated regulation of soil infiltration dynamics in eroded Mollisols

**Yang Zhang [a], Zhonglin Pang [a], Jing Chen [a], Xiangwei Chen [a], Enheng Wang [a,*]**
[a] *College of Forestry, Northeast Forestry University, Harbin, 150040, China*

**ABSTRACT**

Water infiltration is a fundamental hydrological process in terrestrial ecosystems, influencing surface runoff, soil erosion, plant growth, and groundwater recharge. Although vegetation restoration is widely recognized for improving soil infiltration, how root-soil interactions respond to erosion-induced changes in soil profile stratification and related properties, and how these responses affect the hydrological effectiveness of vegetation restoration, remain poorly understood. In this study, we simulated the topsoil loss due to erosion by constructing soil columns with varying thicknesses of the black soil layers (30 cm, 20 cm, 10 cm, and 0 cm), representing a stage of no erosion, mild erosion, moderate erosion, and severe erosion. This gradient was achieved by layering different proportions of surface black soil and underlying depositional subsoil. We then compared soil infiltration rates and patterns across the erosion gradient under bare soil conditions and with four perennial herbaceous species: two Poaceae (*Festuca arundinacea* and *Bromus inermis*) and two Fabaceae (*Medicago sativa* L. and *Astragalus adsurgens*). Results showed that in the absence of vegetation, intensified black soil erosion reduced infiltration rates by more than 60% and shifted infiltration patterns from matrix flow to localized preferential flow. Notably, these preferential flow paths, initiated by unstable cracks, were transient and contributed minimally to overall infiltration. Meanwhile, vertical water infiltration was restricted, while near-surface lateral flow was enhanced, particularly under moderate erosion (10 cm black soil layer), where the effect was most pronounced. The effects of different herbaceous species on infiltration rates and water flow behavior varied depending on root morphology and erosion severity. Fabaceae species, with their well-developed taproot-lateral root systems, consistently increased infiltration rates by13.36%–90.91% across all erosion levels, promoted deep water infiltration and recharge (maximum stained depth increased by > 60%), suppressed lateral flow (stained width-to-depth ratio decreased by > 30%), and significantly enhanced the development of stable preferential flow (preferential flow fraction increased by > 100%) under moderate and severe conditions. In contrast, Poaceae species, characterized by fibrous root systems, improved infiltration rates and promoted preferential flow only in non-eroded and mildly eroded soils, but their effectiveness was generally lower than that of Fabaceae. This study highlights the importance of matching plant types to erosion severity when designing vegetation-based restoration strategies for degraded black soils. Such matching is critical for effectively restoring infiltration capacity and hydrological function. These findings provide valuable insights for developing targeted soil hydrological restoration and water resource management strategies in Mollisols and other regions with similar soil profiles and climatic conditions.

**ABSTRACT**

Enhancing soil structure is fundamental to sustaining soil functions and overall soil health, and its development is strongly governed by climate, land use, and soil type. This study evaluated near-saturation water retention as an indicator of soil structural condition across four climatic regions under long-term land use and compared these effects with a single application of an anionic polyacrylamide (PAM).Soils were collected from humid (USA: crop conventional tillage, CT; crop no-till, NT; grass; forest), temperate (Ethiopia: crop CT; grass; bush; forest), semi-arid (Turkey: crop CT; grass; forest), and arid (Israel: crop CT; orchard; virgin) regions, comprising 272 samples with textures ranging from sandy loam to clay. In each region, three crop CT soils with contrasting textures were treated with PAM at 0, 25, 50, 100, & 200 mg $L^{-1}$ (60 samples). Structural responses were quantified using the high-energy moisture characteristic (HEMC, 0–50 hPa). Water-retention curves were described using modified van Genuchten parameters (α and n), and soil structural stability was expressed as a stability index (SI). Treatments produced distinct curve shapes (α = 0.036–0.099 $hPa^{-1}$; $n$ = 7.1–20.6), reflecting shifts in macropore domains (>250, 125–250, and 60–125 µm) associated with large- and small-macroaggregate stability (SI = 0.002–0.060 $hPa^{-1}$).Higher soil organic carbon (SOC; crop CT < crop NT < grass/bush/orchard < forest/virgin) and increasing PAM rates increased α (0.054–0.096 $hPa^{-1}$) and SI (0.004–0.059 $hPa^{-1}$), while decreasing $n$ (16.0–6.3). The magnitude of these responses depended on soil texture, soil type, and climatic region. SI correlated strongly with SOC or the SOC/clay ratio in humid and temperate regions, and with SOC and clay content in semi-arid and arid regions. Crop CT soils exhibited the lowest SI, typically 2–4 times lower than other land-use types, whereas PAM application at 25–50 mg $L^{-1}$ increased SI (0.007–0.033 $hPa^{-1}$) to levels comparable with crop NT, grass, bush, or orchard soils (0.009–0.032 $hPa^{-1}$). Higher PAM rates (100–200 mg $L^{-1}$) further increased SI (0.014–0.042 $hPa^{-1}$), reaching values comparable to forest or virgin soils (0.014–0.059 $hPa^{-1}$), with strongest effects in medium- and clay-textured soils, and drier regions and, where PAM often exceeded SOC effects. Across all climates, long-term NT or grass soils with SOC ≥ 2 g $kg^{-1}$ and soils treated with 25 mg $L^{-1}$ PAM exhibited similar SI values, indicating a practical threshold for structural quality (SI ≥ 0.010–0.020 $hPa^{-1}$). Exponential relationships between SI and α or $n$ (α: $R^2$ = 0.85; $n$: $R^2$ = 0.64; $p < 0.001$) provide a quantitative basis for (i) assessing soil SI, and interpreting land-use effects on pore- and aggregate-size distributions; (ii) defining rational PAM rates in conservation agriculture, and (iv) the development of resilient soil structure, accelerated SOC accumulation, and site-specific management strategies, particularly for weakly structured and degraded soils.

# An analytical solution for measuring thermal properties with heat pulse method under convective boundary conditions at the soil-atmosphere interface

**Tianyue Zhao*, Yili Lu, Tusheng Ren**

*Department of Soil & Water Sciences, China Agricultural University, Beijing China 100193*

*E-mail: zhaotianyue@cau.edu.cn

**ABSTRACT**

The Dual-Probe Heat-Pulse (DPHP) method, typically relying on the infinite line heat source model with adiabatic boundary conditions (ILS-ABC), is widely used to measure thermal properties at the soil–atmosphere interface. However, strong surface convection can induce significant errors in the ILS-ABC model, even for shallowly buried sensors. To address this, we developed a modified analytical solution incorporating convective boundary conditions (ILS-CBC) using the Green's function method to accurately determine thermal conductivity ($\lambda$) and heat capacity ($C$). The applicability of this new model for thermal property inversion was verified via finite element simulations and DPHP experiments. Theoretical analysis demonstrates that neglecting convective flow (i.e., using the ILS-ABC solution) causes errors in thermal conductivity to increase non-linearly with the convective heat transfer coefficient ($h$). For a sensor at a 1-mm depth, errors exceeded 20% when $h > 5$ W·m$^{-2}$·K$^{-1}$. The ILS-CBC method significantly improves measurement accuracy in the near-surface layer (0–5 mm) under strong convection ($h$ = 5–50 W·m$^{-2}$·K$^{-1}$). This solution offers a robust tool for studying surface energy balance and heat exchange processes at the soil–atmosphere interface.

# Variation in soil hydraulic properties under different land use in long term experimental plots across Canada

**Yuhong Zhou[1], Asim Biswas[1], Hitesh Vasava[1]**

[1]School of Environmental Sciences, University of Guelph, Guelph, ON N1G 2W1, Canada

Email: yzhou44@uoguelph.ca

**ABSTRACT**

The understanding of soil hydro-physical properties is critical in addressing the current issues in hydrogeology, plant growth, soil health and agricultural sustainable development. Soil hydraulic properties regulate water movement and nutrients transport and are significantly influenced by different land management practices (tillage/no tillage, crop rotation, residue management and fertilization regimes). Although there are extensive research on different soil management practices, a major gap still remains in understanding how long-term treatments interactively and persistently alter soil hydraulic properties. How stable is saturated hydraulic conductivity (Ks) and soil water retention curves （SWRC）after over decades continuous land management? How does long-term land use affect the recovery of soil hydraulic properties after disturbance? How soil hydraulic resilience response to modified soil structure, especially for compacted soil? To answer these proposed questions, soils under different treatments (Tillage system and crop rotations) with consistent management were collected from Canadian long-term research experimental plots. Topsoil (0-15 cm) and subsoil (15-30 cm) samples including intact soil cores and bulk soils were analyzed for soil hydraulic properties: Ks, SWRC ,bulk density, field capacity, permanent wilting point, total available water and pore-size distribution. Conventional pressure plates were used to measure SWRC and Permeameter apparatus was used to determine Ks. Classic Van Genuchten model was applied to estimate and fit the curves of SWRC. Visible and near-infrared (Vis-NIR) spectroscopy was used to rapidly predict the estimation of SWRC and provide comprehensive assessment on various soil properties. Results shows that long-term management practices significantly altered soil structure and hydraulic behavior with higher bulk density, higher total porosity, uneven pore size distribution and reduced saturated hydraulic conductivity. Bulk density in subsoil layer is higher than that in topsoil. Soil cores in subsoil layers were easier saturated than topsoil samples, indicating compacted soil formation from upper layers. These findings demonstrate that long term sustained management practices can lead to persistent changes in soil hydraulic properties, with negative implications for soil water availability, soil health and ecosystem resilience. The better understanding of the variation of soil hydraulic properties will provide suggestions to restore soil function, recover soil hydraulic properties and achieve long-term soil management goal.

**Keywords:** soil hydraulic properties, long-term treatments, soil structure, soil water retention curves, saturated hydraulic conductivity.

# Impacts of model root exudates (Pectin and Oxalic Acid) on multiscale soil structural, hydraulic, and surface properties

**Hui Ao[1*], Graeme Paton[1], Paul Hallett[1]**

[1] *University of Aberdeen（School of Biological Sciences, Aberdeen, United Kingdom )*

* r05ha24@abdn.ac.uk

**ABSTRACT**

Roots excrete mucilage and organic acids as rhizodeposits, which due to their distinct physicochemical properties have gelling and dispersion effects on soils. Along a growing root, these rhizodeposits will interact, but their combined impact on soil physico-chemical behaviour has received limited study. Here pectin simulated mucilage, and oxalic acid simulated organic acids, both identified in natural root exudates.

At the macroscale, soil core experiments were conducted under controlled water potentials and compression loads to assess changes in soil mechanical properties (compression characteristics, hardness, elasticity, and penetration resistance) and soil water properties (water content, sorptivity, and repellency); At the mesoscale, soil aggregate stability was determined via Le Bissonnais methods (fast wetting, slow wetting, and mechanical stirring) to elucidate stabilization mechanisms. At the microscale, soil surface properties (surface potential, charge density, specific surface area) and interparticle forces (electrostatic repulsion, hydration repulsion, van der Waals forces) were measured.

Macroscale results at 200 kPa compression (tractor wheel–like) and -50 kPa water potential showed pectin and pectin-oxalic acid mixed exerted the strongest mechanical effects. Pectin decreased soil hardness by 25.6%, increasing to 36.1% when combined with oxalic acid, whereas oxalic acid alone reduced hardness by only 13.9%. Penetration resistance showed a similar trend, with the mixed treatment decreasing penetration by 47.5%, compared to 32.4% for pectin alone. Pectin treatments also markedly enhanced soil water retention, consistent with hydrogel behaviour, whereas oxalic acid reduced water repellency under dry conditions, indicating a surfactant effect. These effects intensified with increasing compression and decreasing water potential., highlighting the role of rhizodeposits in alleviating drought- and compaction-induced stresses.

Mesoscale aggregate stability tests showed that under fast wetting conditions, pectin and pectin-oxalic acid mixtures improved aggregate stability by 62.5% and 67.18%, respectively, whereas oxalic acid alone slightly reduced stability and consistently decreased aggregate stability under slow wetting and mechanical stirring conditions. Microscale analyses showed that oxalic acid increased specific surface area without significantly altering surface charge number, resulting in a 6.8–12.1% reduction in soil surface potential and enhanced interparticle repulsion. These microscale changes explain the observed aggregate destabilization and weaker macroscopic structural improvements under oxalic acid treatment.

Overall, these results demonstrate that mucilage-dominated rhizodeposits stabilize soil structure across scales, whereas organic acids promote particle repulsion and structural destabilization, emphasizing the importance of rhizodeposit composition in regulating soil physical resilience.

## ABSTRACT

Soil pores are critical in regulating water transmission within the arable layer of paddy fields, with their structure and characteristic parameters significantly influenced by the duration of rice cultivation. However, the multiscale evolution of pore structure and corresponding hydraulic properties in paddy fields with varying cultivation histories remains poorly understood. This study employed computed tomography (CT) scanning to systematically analyse the evolution of soil pore structure within the 0-15 cm plough layer at three scales: soil column (resolution > 240 μm), soil core (resolution > 50 μm), and soil aggregate (resolution > 6 μm). The investigation further integrated measurements of saturated hydraulic conductivity and soil moisture characteristic curves to explore the response of soil porosity to hydraulic properties.

Results indicate that with increasing years of rice cultivation, total porosity at both soil column and soil core scales decreased significantly, from 10.69% and 9.5% to 1.52% and 4.38% respectively. Conversely, the pore structure at the soil aggregate scale, primarily governed by root activity, exhibited no discernible temporal variation. Node density fluctuated downward with increasing cultivation duration at both soil column and soil core scales, while at the soil aggregate scale it initially increased before decreasing; The hydraulic radius progressively increased with tillage duration at the soil column scale (from 0.4053 mm to 1.9565 mm), exhibited an initial increase followed by a decrease at the soil core scale, and showed an initial decrease followed by an increase at the soil aggregate scale. Connectivity gradually decreased with tillage duration at the soil column scale, while both soil core and soil aggregate scales displayed an initial increase followed by a decrease. Fractal dimension, mean tortuosity, and length density showed no discernible trend with tillage duration. As the observation scale shifted from soil columns to aggregates, the proportion of biopores progressively increased while the proportion of non-biopores correspondingly decreased (Fig.1). Concurrently, node density, surface area density, and length density rapidly increased, whilst hydraulic radius gradually diminished. Pearson correlation analysis indicates that saturated hydraulic conductivity exhibits significant correlations with mean macropore volume (r = 0.90), average angle (r = 0.94), and surface area density (r = 0.89) at the soil core scale, while showing weaker correlations with pore characteristics at the soil column and soil aggregate scales. This study elucidates the evolutionary patterns of pore structures and multi-scale hydrological responses in paddy soil arable layers over cultivation timelines, providing theoretical References for soil structure improvement and irrigation management in rice paddies.

# Effect of organic matter on isothermal thermogravimetric profiles in the low temperature range (60°C–200°C)

**Zizheng Deng, Chong Chen, Jianying Shang, Hu Zhou**

*College of Land Science and Technology, China Agricultural University, Beijing, China 100193*

Presenting Author (Email: Dengzz1996@126.com)

**ABSTRACT**

Knowledge about how organic matter affects isothermal thermogravimetric (TG) profiles of soils within the low temperature range (60 - 200°C), and about how these profiles relate to physicochemical properties, remains limited. In this study, isothermal TG profiles were measured for mixtures of three representative clay minerals with humic acid (HA) at different mixing ratios( 0%, 2%, 4%, 6%, and 8%), and for thirteen soils with different organic carbon contents(1.16% - 4.72%), before and after OC removal, within 60°C to 200°C. Except for pure kaolinite, which showed a linear increase in mass loss (ML) with temperature ($R^2 = 0.98$), all other samples exhibited a logarithmic increase in ML ($R^2 > 0.98$). For kaolinite, adding HA increased ML, with a more significant increase observed in the 60 - 105°C range compared to 105 - 200°C. For illite (IL), HA concentrations below 4% had little effect on the TG profile, while HA content above 6% significantly enhanced ML, particularly in the 105 - 200°C range. In contrast, HA had a minimal impact on the TG profile of montmorillonite (Mon). For most soil samples (11 out of 13), the presence of OC increased ML at different temperatures, with a more significant increase observed in the 60 - 105°C range compared to 105 - 200°C. Within 60 - 200°C, water content of all investigated samples decreased linearly with increasing pF (logarithm of negative water potential), and this relationship was well described by the Campbell and Shiozawa (1992) model ($R^2 > 0.96$). For KAO, the reciprocal of parameter SL, 1/SL showed a linear relationship with HA content ($R^2 = 0.94$), whereas for IL, 1/SL showed a quadratic relationship with HA content addition ($R^2 = 0.99$). For soils, the presence of OC reduced the explanatory power of the linear models built between 1/SL and CEC, $SSA_{N2}$, and $SSA_{H2O}$.

# How Water-Salt Stress Reshapes the Rhizosphere and Regulates Growth in Suaeda salsa

**Bindeliya, Haigang Li, Wencan Zhang***

*College of Resources and Environmental Sciences, Inner Mongolia Agricultural University, Hohhot, China*

* wencanzhang@imau.edu.cn

**ABSTRACT**

*Suaeda salsa L.* is a halophyte in arid saline–alkali landscapes and a promising species for vegetation establishment. Rhizosphere responses, including soil physical shifts and exudate-driven microbial assembly, remain insufficiently quantified. Here we subjected *S. salsa* to four soil-water levels and four salinity levels (0–200 mM NaCl) and contrasted rhizosphere versus bulk soil properties. We quantified volumetric water content (VWC), penetration resistance (PR), electrical conductivity (EC) and pH, and integrated untargeted metabolomics with amplicon sequencing to resolve exudate profiles, inferred pathways and microbiome shifts. Moderate salinity (50–100 mM NaCl) increased shoot and root biomass and enhanced total root exudation. Across treatments, the rhizosphere exhibited higher PR than bulk soil, and the rhizosphere–bulk PR contrast increased with drought intensity. EC was lower in the rhizosphere than in bulk soil, whereas rhizosphere pH was higher. Redundancy analysis identified VWC, PR and pH as the dominant predictors of plant performance. Structural equation modelling showed that rhizosphere conditions, microbial diversity and core metabolites jointly explained 93% of the variation in plant growth, with total root length and pH exerting significant positive direct effects. Responses were threshold-dependent: from 0–100 mM NaCl, low salinity promoted root development and increased exudation, supporting growth; at ≥200 mM NaCl, plants enhanced salt–drought tolerance by downregulating the tricarboxylic acid cycle (lower energy demand) and enriching Proteobacteria and Bacteroidetes. These findings connect plant phenotype, exudate–microbe interactions and rhizosphere physical conditions, offering a soil-physical perspective on halophyte adaptation and guidance for restoration and rhizosphere management in arid saline–alkali lands.

## ABSTRACT

Repeated flooding and drainage create wet–dry cycles that influence soil structure in paddy fields. Shrinkage cracking and connected macropores enhance preferential flow and increase deep percolation, whereas a pore system dominated by small pores promotes matrix flow with slower, more uniform infiltration. Therefore, pore structure and pore size distribution are important for water movement and drainage management in paddy soils. In recent years, X-ray computed tomography (X-ray CT) has been widely used as a rapid, non-destructive method to quantify soil pore structure in three dimensions. However, there are still few studies that link soil physical properties such as saturated hydraulic conductivity ($K_s$) in paddy soils to specific, quantitative structural parameters of the pore network. Furthermore, the long-term effects of organic fertilizer and soil amendment practices on paddy soil pore structure have rarely been directly observed. We hypothesize that long-term fertilizer management can reshape paddy soil pore structure and thereby change $K_s$, and we aim to use X-ray CT to identify the key pore-network parameters to explain saturated water flow.

Soil column samples (height: 5cm; 100 cm³) were collected from the paddy field in Fukushima, Japan, where four fertilizer managements were prolonged for more than 80 years: soil amendment (SA; NPK plus compost and soil ameliorants, i.e., silicate lime and fused phosphate), no chemical fertilizer (NF), mineral fertilizer (NPK), and compost (C). The column samples were collected at 2-7, 10-15, and 20-25 cm depths. Samples were equilibrated to a given matric potential targeting an equivalent pore diameter to standardize the macropore domain prior to scanning. Samples were imaged by X-ray micro-CT (voxel size 17.6 μm), and we quantified macropore volume and numbers, pore-size metrics (mean, minimum and maximum diameter), and pore network tortuosity. Finally, saturated hydraulic conductivity (*Ks*) was measured.

In the surface layer (2-7 cm depth), total macropore volume showed a clear tendency: SA was highest, followed by C, NPK and NF; SA was significantly higher than NF ($P < 0.05$). Fertilization affected soil pores not only in terms of volume but also in pore number. NF showed both smaller pore volume and fewer pore numbers. The effect of fertilizer management on $\log_{10}(K_s)$ was depth-dependent: treatment differences were clear between 2–7 and 10–15 cm. Across all samples, $\log_{10}(K_s)$ was positively correlated with total macropore volume ($r \approx 0.64$) and through-going macropore volume ($r \approx 0.47$), suggesting that permeability was governed primarily by the volumetric contribution of connected macropores rather than pore number.

Our results suggest that organic inputs and soil amendment (C and SA) tended to increase macropore volumes in the upper soil, enhance the complexity of the pore network and then affect hydraulic conductivity. However, the effect gradually weakened with increasing soil depth.

# Transformation of Agro-Physical Soil Properties During Urbanization: A Case Study in the Republic of Adygea

2 Soil Biology, Moscow State University, Moscow, Russia

taxievaao@gmail.com

**ABSTRACT**

Amid accelerating urbanization, soil serves as a key urban-ecosystem component, enabling carbon sequestration and water-air regimes for plant. Agro-physical properties: granulometric composition, bulk density, hydraulic conductivity directly influence green space quality. Land use changes trigger soil properties transformation, driven by urban-specific factors distinct from natural landscapes.

This study examines soil changes in recreation areas in comparison with background (undisturbed) areas.The purpose was to investigate the transformation of agro-physical soil properties during urbanization, using the Republic of Adygea as a case study. Key tasks included: landscape-ecological and functional zoning, field measurements of physical properties and laboratory analysis.

Study sites encompassed soils from Giaginsky and Maikop districts in Adygea, in two variants: central park areas of Giaginskaya and Dakhovskaya, and sites outside settlements. Besides the study was augmented by a Maikop city park site, where freshly imported lawn substrate and its properties after one year were assessed. Instruments included 101 $cm^3$ cylinders (Kachinsky method), micropenetrometer and 10 cm tubes for filtration coefficient. Granulometric composition was analyzed via laser diffraction on a Mastersizer 3000E with ultrasonic pre-treatment; solid phase density by pycnometry; and carbon content by dry combustion on an express analyzer.

Soils in Giaginsky are leached chernozems, with humus horizons exceeding 65 cm depth in both profiles. In the foothill Dakhovskaya gray forest soils are placed.

The most pronounced differences between urban and background soils occur in surface horizons. Bulk density in all variants is low despite heavy granulometry, similarly distributed in urbanized and background profiles: 0.99 $g/cm^3$ at surface, rising to 1.3 $g/cm^3$ at 30 cm depth. In Dakhovskaya park, the pattern reverses: 1.38 $g/cm^3$ at the upper layer and 1.14 $g/cm^3$ at 30 cm, possibly due to recreational loading. Penetration resistance <3 MPa, classifying these as well-structured soils. Exceptionally high and very high Eggerlsmann filtration rates prevail in upper horizons, declining to high and moderate values with depth. Urbanized soils exhibit slower water permeability than background ones.

At the Maikop site surveyed in 2024 and re-assessed in 2025, compaction changing from 1.2 to 1.3 $g/cm^3$, penetration resistance rising from 29.4 to 273.6 kPa, and filtration coefficient dropping from 42.5 to 19.3 cm/day. These shifts indicate gradual deterioration of water-air properties for plant growth. Nonetheless, values remain within optimal ranges, below critical limits.

[3] *CSIRO Agriculture and Food (Canberra, Australia)*

*simhoff@fca.unl.edu.ar

**ABSTRACT**

In modern agriculture, soil compaction can increase nitrous oxide ($N_2O$) emissions by restricting the water movement, thereby promoting anaerobic conditions that favor denitrification. Controlled traffic farming (CTF) has the potential to mitigate $N_2O$ emissions by confining soil compaction to permanent traffic lanes (PTL). The aim of this study was to evaluate the effect of CTF systems, which use commercially available machinery, on soil $N_2O$ emissions. The study was conducted on two Typic Argiudolls located at Aurelia and Videla sites, in the central Pampas of Argentina. Measurements were carried out in both permanent traffic lanes (PTL) and permanent crop beds (PCB) within the on-farms experiments cultivated under no-tillage. Two treatments with three replications were established, corresponding to different levels of soil compaction applied to the PTL: T0, soil without additional traffic (historical compaction), and T1, soil subjected to additional compaction with a harvester combine until penetration resistance reached 4 MPa. Within each plot, two sampling positions were defined (PTL and PCB), resulting in a total of 12 sampling points. Soil water content, air and soil temperature, bulk density, nitrate concentration, and $N_2O$ fluxes were monitored over one month during autumn and summer. The results showed that $N_2O$ fluxes were influenced by water-filled pore space, soil temperature, and the initial level of compaction applied to the PTL. Emissions from PTL were significantly higher than those from PCB during autumn (Aurelia), whereas no significant differences were observed in summer (Videla). Cumulative $N_2O$ fluxes at the Aurelia site, were 240 (PTL-T1), 61 (PCB-T1), 158 (PTL-T0), and 51 (PCB-T0), all as g $N_2O$-N $ha^{-1}$. Cumulative emissions from PTL were significantly higher than those from PCB. At the Videla site, cumulative $N_2O$ fluxes were 22 in PTL-T1, 29 in PTL-T0, 18 in PCB-T1, and 20 g $N_2O$-N $ha^{-1}$ in PCB-T0, respectively. Cumulative $N_2O$ emissions at this site showed no differences between treatments or sampling position, and the overall average was 22.5 g $N_2O$-N $ha^{-1}$. Overall, the CTF system reduced soil $N_2O$ emissions by approximately 50% under wet soil conditions, even at low soil temperatures. In contrast, when water-filled pore space was low, $N_2O$ emissions remained close to background levels and were not affected by soil temperature.

# Bearing capacity of an Argiudoll under direct seeding and controlled machinery traffic amended with soluble calcium

**Eugenia Oggero[2], Juan Nicolier[2], Josefina Masola[2], Mauro Alisio[1], Carlos A. Alesso[2], Silvia Imhoff[1*]**

[1] *Instituto de Ciencias Agropecuarias del Litoral (ICiAgro Litoral-CONICET-UNL, Esperanza, Argentina)*

[2] *Facultad de Ciencias Agrarias (UNL, Esperanza, Argentina)*

*simhoff@fca.unl.edu.ar

**ABSTRACT**

Machinery traffic is one of the main causes of soil compaction in Argentina. Soils with high silt content that have lost organic matter and binding cations such as $Ca^{+2}$ are susceptible to compaction. Replenishing binding cations is important to maintain the internal aggregates strength, but it is also essential not to exceed the soil bearing capacity, a value calculated from the compression curve and known as pre-compression pressure (σ). One alternative to avoid soil compaction is controlled machinery traffic (CMT), which is little used in Argentina. The objective of this study was to evaluate the effect of soluble calcium application on the soil bearing capacity of a typical Argiudoll located in Santa Fe (Argentina) cultivated under no-till and eight years of CMT use. 1,500 kg/ha of a calcium sulfate plus calcium hydroxide (70:30) amendment was applied to raise the $Ca^{+2}$ saturation of the cation exchange capacity to 70%. In plots, three compaction treatments were established in the permanent traffic lanes (PTL): PTL-T0 (control-no initial compaction), PTL-T1 and PTL-T2 (PTL initially compacted to reach 2 and 4 MPa of mechanical resistance, respectively), each one with their corresponding permanent crop bed (PCB) PCB-T0, PCB-T1, and PCB-T2. The calcium amendment was applied to half of the plots following a completely randomized block design with split plots and three replicates (n=18). Eight months after the $Ca^{+2}$ application, cylinders (7.5 cm diameter and 2.5 cm height) were collected from the center of each PTL and PCB at 0-10 cm, 10-20 cm, and 20-30 cm depth and equilibrated at 10 kPa of tension. Compression curves were obtained using an automated consolidometer and σ values were calculated. In the PCB, $Ca^{+2}$ application decreased σ: 54 vs. 68 kPa (0-10 cm), 112 vs. 149 kPa (10-20 cm), and 126 vs. 164 kPa (20-30 cm). In contrast, in PTL from 0-10 cm, $Ca^{+2}$ significantly increased σ: 120 vs. 90 kPa in PTL-T0; 128 vs. 111 kPa in PTL-T1; and 183 vs. 152 kPa in PTL-T2. At depths of 10-20 and 20-30 cm, σ was neither affected by $Ca^{+2}$ nor by PTL treatments, with average values of 146 and 190 kPa, respectively. Calcium application in the first 10 cm increased the soil bearing capacity in the PTL facilitating machinery traffic, while in the PCB it promotes soil structure regeneration, which is favored by the absence of compaction associated with the CMT system. Further evaluations are required to verify the effect of calcium on structural stability in the PCB and the evolution of σ in the PTL with successive traffic.

**Key-words:** calcium sulfate, calcium hydroxide, permanent traffic lanes, permanent crop bed, pre-compression pressure

## ABSTRACT

Soil erosion represents a global environmental challenge that directly influences cropland quality and the sustainable use of soil resources, but indirectly affecting the turnover of soil C, climate change, and food security.The red soil region in southern China, under the combined influence of natural and anthropogenic factors, has become one of the most severely affected areas in terms of soil erosion. Physical soil crusts (PSC), defined as dense structural layer formed on the surface of bare or very low-cover land due to raindrop splashes or runoff, alter soil surface characteristics and significantly affect water infiltration and surface runoff generation. Although existing studies have demonstrated the widespread occurrence of PSCs in red soil regions due to local rainfall patterns and climatic conditions, the dynamic evolution of PSCs during rainfall events remains poorly understood. Furthermore, grass hedgerow serves as an effective biological measure for mitigating soil erosion by reducing surface flow velocity and erosive power through their aboveground biomass and root systems, while simultaneously enhancing soil physicochemical properties, fertility, and nutrient retention. However, the role of grass hedgerow measure in modulating the development of PSCs and their effectiveness in controlling erosion at different stages of crust formation remains unclear.

This study investigated the formation and erosion characteristics of PSCs developed on Quaternary red clay in typical red soil regions of southern China. Field-simulated rainfall experiments were conducted at an intensity of 30 mm/h. The research consisted of three components:
(1) Crust development process: PSC samples were collected at rainfall durations of 10, 30, 60, 90, and 120 min using PVC cutting rings. The pore structure and crust thickness were quantitatively characterized through X-ray computed tomography (CT) scanning, revealing the developmental process and structural characteristics of red clay crusts.
(2) Influence of grass hedgerows: Micro-plots were established within grass hedgerow systems. After 60 min of rainfall, soil samples were taken at varying distances from the hedgerows and analyzed via CT to assess spatial differences in pore parameters and crust thickness, thereby evaluating the mitigating effect of hedgerows on crust formation.
(3) Erosion response of crusted surfaces: Pre-formed crusts at different developmental stages (induced by 10–90 min of prior rainfall) were subjected to simulated rainfall to measure runoff and sediment yields. The total production of runoff and sediment was calculated for analyzing the effects of different stages.

Key findings from this study include: (1) The development of physical crusts in red clay exhibits distinct temporal stages: an initial stage characterized by particle detachment and pore filling, a middle compaction stage driven by raindrop impact, a late stabilization stage, and a final erosion stage. During crust formation, the thickness of PSC initially increases before stabilizing. The developmental trend fits a cubic equation: $y = 10.17 - 4.69x + 2.49x^2 - 0.30x^3$ ($R^2 = 0.8823$). At each developmental stage, the two-dimensional and three-dimensional pore structures of the crusts display unique morphological features. (2) Grass hedgerows significantly affected the spatial distribution and structural heterogeneity of soil crusts, with the crusts thinnest within the hedgerow and thickest between the hedgerows. (3) The development of PSCs accelerated the generation of runoff and suppressed sediment yield, with runoff increasing exponentially and sediment production stabilizing when a threshold of crust thickness was reached. Incorporating crust thickness into sediment-prediction models improved estimation accuracy by 18.6 % compared to conventional models based on rainfall indices, while maintaining comparable runoff-prediction performance.

These findings indicate the dual role of PSCs in promoting runoff but limiting soil loss, providing fundamental insights for optimizing hedgerow design, managing soil crust, and designing strategies to control erosion in sloping cropland in the southern red-soil region of China.

# Interfacial hydrodynamic isotope fractionation of infiltrating rainfall in soil pore water is independent of evaporation

**Peng Zhao1,2*, Junxiong Yuan1, Yi Li1 and Genxu Wang2**

[1] *(College ofForestry, Sichuan Agricultural University, Chengdu, China.)*

[2] *(College of Water Resource and Hydropower, Sichuan University.Chengdu, China)*

E-mail Address: zach_zhao@163.com

**ABSTRACT**

Quantifying how rainwater infiltration modifies stable isotope composition in soil pore water is crucial for traci ng critical zone water movement. Tr aditi-onally, isotopic differences are a ttributed to evaporative fractionation or sampling artifacts. However, grow ing evidence suggests non-evaporativ e fractionation occurs during water movement, with underlying physics u nclear.

We monitored intact soil columns un der natural rainfall at high temporal resolution, jointly measuring seepage flux (Q) and drainage water isotopes (δ18O, δ2H). Data reveal a robust th reshold pattern: faster seepage consist ently correlates with more depleted i sotopes, unexplained by evaporation or mixing alone. Specifically, signific ant negative correlations exist at low flux ($Q < 0.2$ mm ·min-1·cm-2; δ2O: $r \approx -0.33$, $p < 0.001$), but disappear at high flux ($Q \geq 0.2$). Drainage data p lot above the Local Meteoric Water Line in dual-isotope space.

We propose the Interfacial Hydrodyn amic Fractionation (IHF) hypothesis. At low Q, prolonged pore-water int erface contact preferentially mobilize s lighter isotopologues, transiently re taining heavier ones, yielding deplete

d drainage. Above a critical Q, shortened residence times "short-circuit" matrix exchange, making efflue nt isotopes resemble input rainfall. IHF is a transport-controlled, non-equilibrium process independent of phase change.

This finding challenges frameworks attributing isotopic offsets solely to evaporation or mixing. IHF provides a hydrodynamic basis for ecohydrological separation, implying that estimating evaporative losses and recharge sources must account for flux-dependent fractionation. Future work should test IHF's generality across soils and climates and integrate it into models to improve water cycle predictions under climate change.

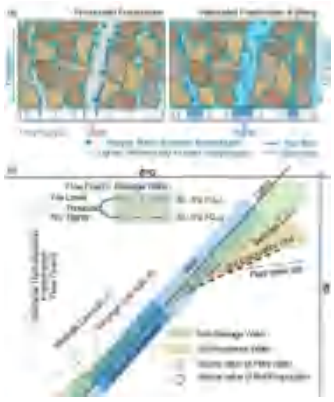

Figure. Flux-threshold interfacial hydrodynamic fractionation (IHF) in vadose-zone seepage: comparison with LMWL and SEL. a Pore-scale conceptual model. Left: Low flux enhances interfacial exchange, retarding heavier isotopologues at interfaces while mobilizing lighter ones. Right: High flux shortens residence time, muting fractionation. b Seepage-line framework. If IHF is widespread, source-value estimates based on LMWL intersections require reassessment. We define Seepage Line-I (low flux) and Seepage Line-II (high flux) to reflect flux-dependent behavior, highlighting flow-path divergence and incomplete matrix exchange.

# Pore Structure–Controlled Water and Solute Transport in Agricultural Soils of Plain River Network Areas

**Xiaoqin Sun[1*], Dongli She[1,2], Hongde Wang[1], Xinni Ju[2] and Yongchun Pan[1]**

*[1] College of Soil and Water Conservation, Hohai University, Changzhou,Jiangsu 213200, China*

*[2] College of Agricultural Sciences and Engineering, Hohai University, Nanjing, 210098, China*

*E-mail: sxqhhu@hhu.edu.cn

**ABSTRACT**

The plain river network (PRN) areas are major high-yield agricultural regions in China, where intensive fertilizer and pesticide use has resulted in serious agricultural non-point source (NPS) pollution. Soil pore structure plays a critical role in regulating NPS generation and transport by controlling water flow pathways and solute migration. However, conventional static fractal parameters are insufficient to characterize actual transport pathways within complex pore networks. To address this limitation, we introduced the spectral fractal dimension (d), a dynamic indicator of pore connectivity derived from random walk theory.

Soils from agricultural fields in the Jiangsu PRN region were investigated, covering the spatial continuum from field interiors to field bunds. High-resolution X-ray CT images were used to quantify pore morphology and heterogeneity, including mass fractal dimension ($D_m$), surface fractal dimension ($D_s$), and the dynamic connectivity parameter (d), across different soil depths. Seepage processes were simulated using AVIZO to quantify multidirectional water flow velocities and to evaluate the influence of pore structure on flow redistribution under irrigation conditions. Solute transport parameters were obtained from breakthrough curves and interpreted using the continuous time random walk (CTRW) framework.

The results showed that surface soils exhibited higher pore abundance and greater structural complexity, resulting in higher solute transport velocity (v) and diffusion coefficient (E) than deeper layers. Pore morphology and heterogeneity ($D_m$ and $D_s$) primarily controlled v and E by facilitating preferential flow pathways and enhancing solid–liquid interactions. In contrast, pore connectivity (d) dominated anomalous transport behavior (β) and solute arrival times ($t_1$, $t_2$) by regulating tortuosity and solute retention. AVIZO-based simulations further demonstrated that pore structural differences significantly influenced vertical and lateral flow velocities. These findings highlight the importance of dynamic pore connectivity in assessing subsurface transport processes and NPS pollution risks in PRN areas.

# Microscale biophysical interactions determine environmental microbial ecology

**Gang Wang**[1,2*]

[1] *Department of Soil and Water Sciences, China Agricultural University, Beijing, China*

[2] *College of Resources and Environment, Xinjiang Agricultural University, Urumqi, China*

*gangwang@cau.edu.cn

**ABSTRACT**

Microscale biophysical interactions at numerous interfaces are critical for microbial life and ecological functioning. Combining novel microscale experimental observations with agent-based computational modeling, we illustrate how microbial intrinsic characteristics function to facilitate dispersal and subsequent interactions among microbial populations and with environments. Bacterial active motility emerged as a key trait facilitating dispersal and early-stage colonization. The surface-attached bacterial life-form likely intensified mineral dissolution and thereby enhanced element cycling. As a consequence, it promoted bacterial population proliferation which further reinforced localized interactions between bacteria and minerals. However, the advantages conferred by cell motility were significantly reduced under constrained pore water configuration (drier soil conditions). Under such conditions, non-motile bacteria relied on passive dispersal mechanisms or physical adhesion to colonize the porous surfaces. Furthermore, functional metagenomic profiling of the colonizing microbial populations uncovered a trade-off between growth and dispersal rates. This observed trade-off was incorporated into an agent-based model simulating microbial activity in soil, which explored how correlations between microbial functional genes influence community dynamics during early colonization. The simulations demonstrated that the growth dispersal trade-off is crucial for enhancing and maintaining microbial diversity during colonization of new niches. These microscale quantitative estimations on biophysical interactions provide new insights into mechanistic understanding of microbial functionalities in regulating the biogeochemical processes of soil elements.

## ABSTRACT

To systematically elucidate the mechanisms by which typical land use practices affect soil hydrological functions on the Loess Plateau, this study investigated cropland, grassland, and shrubland through a combination of field in-situ observations and laboratory analyses. The assessment focused on soil physicochemical properties, aggregate stability, and hydraulic characteristics under the three land use types. The results indicated: (1) Surface soil under shrubland exhibited the most favorable physical structure, with significantly higher soil organic carbon content (28.18 g/kg) compared to cropland (7.79 g/kg) and grassland (10.81 g/kg), along with the highest aggregate stability (MWD, R0.25, D) and the lowest bulk density. (2) Shrubland demonstrated the strongest integrated hydrological function, characterized by significantly superior initial water content (18.39%), stable infiltration rate, and water-holding capacity under high suction compared to the other land use types, forming a "soil reservoir" that effectively combines high infiltration capacity with strong water retention and conservation. (3) Correlation analysis revealed that total soil porosity, root biomass, and aggregate stability are key factors regulating soil hydraulic functions. This study demonstrates that prioritizing shrub vegetation in ecological restoration efforts on the Loess Plateau can synergistically enhance soil water conservation and erosion resistance, providing a scientific basis for optimizing regional land use and ecological rehabilitation.

**ABSTRACT**

[Objective] This study aims to investigate the relationship between soil aggregate stability and soil nutrients under different nitrogen and phosphorus fertilizer levels, to provide a scientifically sound fertilization strategy for improving brown soil structure. [Methods] Based on the long-term fertilization experiment of dark brown soil initiated in 1979 by the Heihe Branch of Heilongjiang Academy of Agricultural Sciences, 12 treatments, including no fertilization ($N_0P_0$) as the control and applied agricultural manure (M), straw returning to field (S), and different NP levels: low, medium, and high quantitative fertilization ($N_1P_1$, $N_2P_2$, $N_4P_4$), wheat straw returning to field + different NP levels ($N_1P_1S$, $N_2P_2S$, $N_4P_4S$), agricultural manure + different NP levels ($N_1P_1M$, $N_2P_2M$, $N_4P_4M$) were used in this study. Soil samples from the 0–20 cm layer were collected for each treatment with three replication, and aggregates were sieved into four grades using the wet sieving method. The mean weight diameter (MWD) and geometric mean diameter (GMD) of aggregates were calculated, and soil pH, soil organic matter (SOM) and nutrient content were measured. [Results]Compared with $N_0P_0$, NP treatment significantly increased the proportion of>2 mm soil aggregates (12%-62%), with the change trend being $N_2P_2$> $N_4P_4$> $N_1P_1$. Under NPS treatment, the proportion decreased with increasing NP levels. In NPM treatments, the proportion followed the order of $N_1P_1M$> $N_4P_4M$> $N_2P_2M$. Compared with $N_0P_0$, NP treatment significantly increased the mean weight diameter (MWD) of soil aggregates (14%-45%), with MWD showing the order of $N_2P_2$> $N_4P_4$> $N_1P_1$with NP levels increasing. Under NPS treament, MWD decreased with increasing NP levels. In NPM treatments, MWD followed the order of $N_1P_1M$> $N_4P_4M$> $N_2P_2M$, with $N_2P_2$ exhibiting the largest MWD. Compared with NP treatments, both NPS and NPM treatment significantly increased soil pH and SOM content. Under NP, NPS, and NPM fertilization, pH decreased with increasing NP levels. The SOM content in NP treatments followed the order of $N_4P_4$> $N_1P_1$> $N_2P_2$, while the order in SOM content under NPS treatments was $N_2P_2$> $N_1P_1$> $N_4P_4$. In NPM treatments, the order of SOM content was $N_2P_2M$> $N_4P_4M$> $N_1P_1M$. Among the combincation of organic and inorganic fertilizers, $N_2P_2S$ and $N_2P_2M$ performed well. Correlation analysis revealed a significant negative correlation between soil organic matter content and both MWD and GMD ($p<0.05$), which were contrary to previous studies,this may be attributed to the higher SOM and C/N ratio background values. The random forest model indicated that the carbon-to-nitrogen ratio (C/N) was the most significant factor influencing soil aggregate stability (MWD). [Conclusion] The combination of organic and inorganic fertilizers significantly increased soil pH, significantly suppressed soil acidification, and enhanced aggregate stability. Among the treatments, $N_2P_2M$ and $N_2P_2S$ demonstrated superior effects compared to other fertilization methods.

**ABSTRACT**

Spectral remote sensing enables efficient acquisition of large-scale land surface information and is a key approach for monitoring soil salinity content (SSC). Plastic-mulched cultivation is the main planting practice adopted in salt-affected arid and semi-arid regions to cope with water–heat imbalance, resulting in most areas being covered by plastic mulch or vegetation for the majority of the time, with bare soil periods difficult to capture. At the same time, surface mulching significantly alters the spectral characteristics of croplands, increasing the uncertainty of SSC retrieval using remote sensing. Based on multi-resolution remote sensing data derived from plastic mulch geometric parameters, this study systematically analyzed the spectral features sensitive to SSC under different mulching conditions and evaluated the effects of spatial resolution on SSC spectral responses. Results indicate that under near-ground ultra-high-resolution conditions, the correlation between inter-mulch bare soil spectral features and SSC is weakly influenced by mulch type, and distinguishing mulch types provides limited improvement in inter-variable relationships. In contrast, under multi-resolution settings at the field scale, separating black-mulched, white-mulched, and non-mulched fields significantly enhances the correlation between spectral indices and SSC, with the coefficient of determination ($R^2$) based on the recursive feature elimination (RFE) algorithm increasing by up to 0.28. The highly sensitive spectral indices of non-mulched farmland are generally consistent with those of white-mulched farmland, but differ markedly from those of black-mulched farmland. Regarding scale optimization, the optimal spatial resolution is 1.35 m for white-mulched and non-mulched farmland, whereas black-mulched farmland performs best at 5.4 m. These findings provide methodological guidance and practical approaches to accurately retrieve SSC in plastic-mulched croplands and to determine the optimal image spatial resolution.

**ABSTRACT**

Climate change is exerting profound impacts on hydrological cycles, posing significant threats to agricultural sustainability and water resource security. Quantifying the sensitivity of agro-hydrological processes to climate change is therefore critical for developing effective adaptation strategies. This study employed a calibrated and improved Soil and Water Assessment Tool (SWAT) model and sensitivity analysis to assess the sensitivity and contributions of key climatic factors to major agro-hydrological variables in the North China Plain (NCP) from 1966 to 2016. The region exhibited a marked warming and drying trend, with minimum temperature rising more rapidly (0.56 °C 10 $a^{-1}$) than maximum temperature (0.12 °C 10 $a^{-1}$). While precipitation and solar radiation decreased 3.98 mm 10 $a^{-1}$ and 0.51 MJ·$m^{-2}$ 10 $a^{-1}$, respectively. Actual evapotranspiration ($ET_a$) was more sensitive to air temperature during the winter wheat season but to solar radiation during the summer maize season; Irrigation demand showed strong positive sensitivity to air temperature and solar radiation but negative sensitivity to precipitation; and water yield demonstrated exceptionally high sensitivity to precipitation, especially at the main watershed outlet. Contribution analysis further indicated solar radiation as the dominant factor governing actual evapotranspiration variation, whereas precipitation was the primary driver for changes in water yield. These findings provide a quantitative basis for crafting targeted water management policies, such as optimizing irrigation scheduling and reinforcing flood control infrastructure, to enhance climate resilience in this vital agricultural zone..

# Mechanical Adaptive Feedback Mechanisms of Microbial Colonies to External Physical Pressure

**Mingyu Su[1*], Gang Wang[1,2]**

[1] *Department of Soil and Water Sciences, China Agricultural University, Beijing, China*

[2] *College of Resources and Environment, Xinjiang Agricultural University, Urumqi, China*

*mysu@cau.edu.cn

**ABSTRACT**

External physical pressure, such as desiccation stress induced by drying-rewetting cycles, is common in natural environments, and is critical for bacterial sessile life forms including biofilms. This confining pressure may directly dictate the spatial configuration of mechanical interactions among cells, and subsequently impacts their growth and range expansion. However, how does such external pressure, conspiring with intrinsic cellular characteristics (e.g., mechanosensitivity, cell aspect ratio), function to shape bacterial cell-cell interactions and emergent community structures remains largely unknown.

Employing individual-based and continuum models, we quantitatively illustrate how single cell scale mechanical responses to the physical stress trigger bacterial collective performance including population growth, range expansion and potential transitions into growth-arrested states.

The study specifically investigates how stress-responsive bacteria adjust internal states such as cell-length diversity and spatial reorganization, thereby modifying internal stress generated by cell-cell contacts and tuning the colony's overall mechanical resistance to external isotropic pressure. The stage of colony development critically influences these adaptive outcomes, as the pre-existing internal stress and structural state of the biofilm vary significantly with its size and age. The mechanical framework established in this work provides a theoretical foundation for understanding how soil microbial communities modulate internal stress to enhance mechanical resilience under external physical constraints, offering important insights into the effects of soil physical processes such as drying-rewetting cycles on microbial ecological functioning.

# Impacts of precipitation and heat changes on agricultural water resources and grain production in the North China Plain

**Wang Xin[1],Feng Shen'ao[1],Tan Lili[1,2*]**

*[1] College of Hydraulic and Civil Engineering, Ludong University, Yantai 264025, China; 2 Key Laboratory of Arable Land Conservation in North China, Ministry of Agriculture and Rural Affairs, Beijing 100193, China*

*E-mail xw48438@gmail.com

**ABSTRACT**

Climate change poses severe challenges to water resources and food security. As a vital breadbasket of China, the North China Plain urgently requires quantitative research on the sustainability of its agricultural water resources and the response mechanisms of crop production to climate change. This study employed an improved SWAT(Soil and Water Assessment Tool) model, combined with long-term (1966–2016) meteorological data and multi-scenario simulations, to quantitatively analyze the impacts of changes in precipitation, temperature, and solar radiation on agricultural hydrological processes and crop yields. The results show that from 1966 to 2016, the maximum and minimum temperatures in the study area increased significantly at rates of 0.12°C and 0.56°C per decade, respectively, while precipitation and solar radiation exhibited declining trends. Spatially, the southern region exhibited higher actual evapotranspiration (annual mean 790.4 mm), irrigation water use (annual mean 359.6 mm), and rates of shallow groundwater decline (annual mean 1.9 $m \cdot a^{-1}$) compared to the northern region. Climate change scenario analysis indicated that increased precipitation boosted winter wheat yields, whereas summer maize yields slightly decreased (≤1%) under precipitation increases of 5%–20%. A 20% reduction in precipitation led to increases in irrigation demand and groundwater decline rates by 10.5% and 21.0%, respectively. Rising temperatures primarily exerted negative impacts on crop yields, while changes in solar radiation had a more pronounced effect on maize production. This study provides a scientific basis for optimizing agricultural water resource allocation and formulating climate-adaptive cropping strategies in the North China Plain, with significant implications for ensuring regional food security and sustainable water resource utilization.

*University of Calcutta,35, B.C. Road, Kolkata- 700019, India*

Email address of presenting authors: sanjib_cu@yahoo.co.in

**ABSTRACT**

To investigate the distribution of the electric charges, by the effects sea weed and some non-traditional compost was made by potentiometric titration method of net electric charge measurement for assessing the effects of these composts on rice productivity. For this purpose, soil incubated with sea weed and some nontraditional composts and analyze it on various electro-chemical charge character along with pot and field study on rice production. The surface charge of variable charge constituents depends on the pH and ionic strength of soil solution. Organic carbon strongly affects the variation of negative charge with pH, but sesquioxide or allophone is responsible for positive charge variation. Variable surface charge is attributed to the ionization of functional groups on organic matter, hydrous Fe and Al oxides, and edge sites on clay by protonation and de protonation processes. Soil charge formation is regulated by the nature of organic matter, clay and sesquioxide Sea weed influence more on ZPC shifted it to lower range indicate that it contributes enormous amount of soil charge to soil system that's accelerates ionic movements and rice productivity.

# Floodplain Wetlands as Biogeochemical Filters Following Wildfire

**Sean Fettrow[1], Pauline Sophie Rummel[2], Klaus Koren[2], Will James[1], Mike Wilkins[1], Tim Fegel [1,3], Charles. C. Rhoades[3], Thomas Borch[1]**

*[1]Department of Soil and Crop Sciences, Colorado State University, Fort Collins, CO, USA*

*[2]Department of Microbiology, Aarhus University, Aarhus, DK*

*[3]US Forest Service, Rocky Mountain Research Station, Fort Collins, CO, USA*

## ABSTRACT

Wildfires in high elevation headwater forests are occurring more frequently and at greater severity due to climate change. Within watersheds following wildfire, perennially saturated wetlands may slow surface runoff and help filter sediment, ash, char, and dissolved chemical solutes, all of which cause issues for water quality and downstream water users. To increase retention of surface water, groundwater and sediment, wooden structures that mimic beaver dams have been installed within stream channels and the surrounding floodplain in a watershed within the Rocky Mountains, Colorado that burned during the 2020 Cameron Peak Fire. One objective of this project is to evaluate the potential of montane floodplain wetlands as natural biogeochemical filters following wildfire and further assess how increased saturation from dam installation may alter these processes. To address this objective, we conducted a greenhouse experiment with custom-made rhizoboxes using plants and soil collected from the field site. We introduced a burned (450ºC) soil extract once plants maturated (~3 months) to investigate how biogeochemistry responds to a pulse of pyrogenic material. Furthermore, to understand how in stream structures and the resulting increased floodplain inundation impacts biogeochemistry, we conducted this experiment with three water level treatments: fully flooded, semi-flooded and drained. We quantified in-situ porewater chemistry (i.e., pH, redox, DOC, UV-VIS-EEMs), plant-soil gas flux (i.e., $CO_2$, $CH_4$, $N_2O$, $NH_3$), soil microbial analysis, root growth, along with planar optode $O_2$ soil profile imaging. Our results show that after the addition of pyrogenic material, a significant pulse of $CO_2$ from the soil occurred and lasted for ~1 month. This pulse turned the systems from net sinks of $CO_2$ to net sources. Interestingly, there was no subsequent increase in total porewater dissolved organic carbon (DOC) following addition of the pyrogenic material, but changes to porewater DOC characteristics (i.e., UV-VIS-EEMs parameters) were detected. This indicates that DOC characterization, rather than concentration, drove the increase in soil $CO_2$ flux. Furthermore, we found evidence for plant-mediated transport of $CH_4$ in our systems, as $CH_4$ flux measurements obtained under full light saturation were significantly greater than $CH_4$ flux measurements observed with no light. This points to a mechanism where $CH_4$ may be escaping through leaf stomata when the stomata are open during photosynthesis (i.e., when lights are on) compared to when they are closed (i.e., when lights are off). Our findings exemplify the ability of montane wetlands to act as a natural biogeochemical filter following wildfire and provide insight into the management of floodplains following wildfire. Furthermore, we find that our integrated experimental approach is applicable and adaptable to a wide range of plant-soil settings and scenarios, particularly at the soil-plant-atmosphere interface.

# Potassium mineralization potentials of some soil amendments applied to a degraded tropical Ultisol

**Nnaemeka H. Okoli, and Chioma M. Ahukaemere**

*Department of Soil Science and Technology, Federal University of Technology Owerri, Nigera*

*Email address of Presenting Author: nnaemeka.okoli@futo.edu.ng

**ABSTRACT**

Understanding Potassium (K) mineralization pattern of soil amendments is critical in proper K fertilizer management. This study evaluated the potassium (K) mineralization potential of selected soil amendments applied to a degraded Ultisol during a 90 day incubation period. The objective was to assess the effects of these organic amendments and period of incubation on the release and availability of exchangeable K and to examine the relationships between K dynamics and selected soil properties during a 90-day incubation period. The experiment was arranged in a 4 × 10 factorial experimental set-up fitted in a Completely Randomized Design. Treatments were soil amendments (Control, poultry manure, biosolids, and biochar) and period of incubation (0, 10, 20, 30, 40, 50, 60, 70, 80, 90 days). Physico-chemical properties of both the soil and the amendments were characterized prior to incubation. Exchangeable K was measured at 10 day interval to monitor the rate and pattern of K mineralization. The results showed marked effect of both the soil amendments and period of incubation on K mineralization. The results revealed that all the amendments significantly increased exchangeable K concentrations relative to the unamended control, indicating enhanced nutrient release and improved soil fertility status. Among the treatments, poultry manure exhibited the highest and most rapid K release, reaching a peak concentration at 60 days of incubation, reflecting its high nutrient content and fast mineralization rate. Biochar demonstrated a steady and sustained K release throughout the 90 days, suggesting its long-term potential to maintain nutrient availability and reduce K losses through leaching. In contrast, biosolids produced the lowest increase in exchangeable K, indicating limited contribution to K mineralization. Correlation analysis showed strong positive relationships between exchangeable K, soil pH and exchangeable calcium, implying that amendments that increased soil pH and base cation content enhanced K availability and retention in acidic soils. Negative correlations with sodium and phosphorus suggested possible nutrient interactions or competition among cations. The study demonstrated that poultry manure and biochar are highly effective organic amendments for improving K mineralization, soil fertility, and nutrient balance in acidic Ultisol.

# The effect of endogenous hydrogen on the soils of the degassing sites of the Central Chernozem region of the Russian Federation

**ABSTRACT**

The manifestations of degassing are found on almost all continents and are well deciphered in the satellite images. They are either lightened spots and circles that are clearly visible on the arable land of automorphic soils, or depressions experiencing temporary excessive waterlogging. The diagnostic indicator for their detection is the correct round shape and lightening of the upper humus horizon.

The soils affected by endogenous hydrogen are very different from the soils of the surrounding area, which are similar in hydrothermal conditions. According to our research, an intensive reductive regime is formed in chernozems exposed to hydrogen flux. The acidity increases dramatically, and carbonate neoplasms disappear. With an increase in the total humus content, the upper humus horizon lightens as a result of changes in the composition and properties of humus. The composition of humus in such conditions changes towards a fulvate type, unusual for chernozems, which indicates its high mobility. The presence of a large amount of aggressive fulvic acids in the soil mass is probably one of the reasons for the very strong acidification of the soil profile.

It should be noted that such soils have been studied before, but features mentioned above were attributed to the effect of temporary waterlogging, since the processes of hydrogen degassing were beyond the attention of scientists. A series of model experiments have been conducted to distinguish the effects of the waterlogging factor and the hydrogen flux factor on chernozem soils. The experimental results show that the effect of hydrogen flux and waterlogging on soils will be unidirectional, but different in intensity. Waterlogging slightly reduces the redox potential of the soil (by 100 mV), while (according to NMR13C data) there is a slight change in the fragment composition of humic acids, while incoming hydrogen reduces the redox potential to extremely low values (by 800 mV) and ensures the destruction of the peripheral part of humic molecules without destruction of aromatic clusters. In the presence of a hydrogen stream, the content of non-silicate iron compounds in the soil increases, and their ratio indicates an intensification of the gley process. The removal of organic matter into the soil solution increases, and an increase in the concentration of aluminum in the solution indicates the likely destruction of the crystalline lattices of aluminosilicates, which are part of the solid phase of the soil. These features are clearly reflected in the morphology of the soil profile and indicate the predominant processes of substance removal in soils exposed to intensive flux of endogenous hydrogen.

# Effects of repeated wetting and drying cycles on potassium fertiliser behaviour and nutrient dynamics in diverse soils

## ABSTRACT

Improving soil potassium (K) availability is essential for plant nutrition, but K fertilizer efficiency is estimated to be only 19% globally for cereal crops. Repeated wetting and drying cycles are a defining feature of soils of all agricultural systems and have a marked influence on nutrient cycling and fertiliser behaviour by modifying soil structure, ion diffusion and binding, and redox processes. However, much remains unclear regarding the effects of wetting and drying cycles on K fertiliser behaviour, such as whether the form of K fertiliser applied alters K behaviour. One fertiliser of particular interest is polyhalite, as it co-supplies other cations (Ca and Mg) with K which may potentially reduce K fixation in soils with high fixation capacity.

In this study, we used eight highly diverse soils from Australia, the United States, the United Kingdom, Nigeria and China, dominated by different minerals, such as montmorillonite, illite-smectite, kaolinite and quartz. Soils were treated with polyhalite ($K_2SO_4MgSO_42CaSO_4 \cdot 2H_2O$) or sulfate of potash (SOP) at a rate of 1.20 g K $kg^{-1}$ soil, equivalent to 150 kg K $ha^{-1}$. We simulated the fertosphere conditions (the fertiliser-enriched soil around the granule) to better understand the reactions that drive the availability of K. Soils were then incubated and subjected to various wetting and drying cycles (0, 2 and 8 cycles), alternating between 20 and 80% of water holding capacity (WHC). Each cycle consisted of approximately 24 h of wet incubation followed by 16–20 h of drying at 25 °C.

It was found that repeated wetting and drying cycles substantially altered K partitioning and speciation across these diverse soils. In soils containing minerals with a high capacity to fix K (such as illite and muscovite), wetting drying cycles promoted the fixation of K within interlayer sites. In contrast, soils dominated by highly weathered minerals, such as those from Australia, had minimal K fixation. Other than K fixation, the form of K was most closely related to clay content and cation exchange capacity (CEC) – soils with a high CEC had increased exchangeable K whilst soils with a low CEC had higher concentrations of soluble K. We also examined the effect of the K form supplied (SOP or polyhalite) on K behaviour, with the co-supply of Ca and Mg from polyhalite slightly reducing K fixation by competing for exchange sites and modifying cation equilibria. Finally, preliminary K-edge X-ray absorption near edge structure (XANES) analyses revealed corresponding spectral shifts, confirming the progressive transformation of K speciation under repeated wetting and drying cycles.

Overall, repeated wetting and drying cycles altered K availability in a soil-specific manner. High-clay soils with K-fixing minerals had reduced K availability whilst sandy and highly weathered soils had higher K availability. It was also found that co-supply of Ca and Mg from polyhalite can potentially decrease K fixation.

# Impact of Saltwater Intrusion on Phosphorus Speciation and Mobility in an Agricultural Soil

**Piyapas Sricharoenvech[1,*], Onuma Changmai[1], Worachart Wisawapipat[1], Sompin Mahakhot[2], and Wantana Klysubun[2]**

[1] *Department of Soil Science, Kasetsart University, Bangkok, Thailand*

[2] *Synchrotron Light Research Institute (Public Organization), Nakhon Ratchasima, Thailand*

*piyapas.sri@ku.th, fagrppsr@ku.ac.th

**ABSTRACT**

Saltwater intrusion, resulting from sea level rise, poses threats to agricultural areas along the coastlines by altering soil physicochemical properties and porewater chemical compositions. These changes may affect phosphorus (P) speciation and lability, leading to P release into water bodies and associated environmental impacts. In this study, we utilized synchrotron-based X-ray absorption near edge structure (XANES) spectroscopy in combination with Mehlich-3 (M3) and Hedley sequential extractions to monitor changes in P speciation and mobility in an agricultural soil. A representative agricultural soil was selected from the lower Chao Praya floodplain of Thailand, amended with P in a form of potassium dihydrogen phosphate ($KH_2PO_4$), and saturated for up to 60 days with synthetic water of four salinity levels: 0.05, 0.2, 2, and 5 parts per thousand (ppt). Porewater was collected daily using rhizon samplers to monitor inorganic P ($P_i$) release. The results revealed that soil pH initially decreased and slowly rebounded beyond the initial soil pH for all salinity treatments. Exposure to high water salinity (i.e., 2 and 5 ppt) markedly increased soil electrical conductivity (EC), suggesting salt accumulation, while low water salinity (i.e., 0.2 and 0.05 ppt) slightly reduced soil EC. Chemical extractions showed a decrease in M3-extracted and water-soluble P over time; however, the proportions of these fractions were slightly higher in soil samples treated with high-salinity water compared to the low-salinity treatments, indicating higher soil P availability. This result corresponds with the higher $P_i$ concentrations in the porewater of the high-salinity treatments toward the end of saturation period. Furthermore, our XANES analysis identified iron (Fe), aluminum (Al), and smectitic clay minerals as the primary hosts for P in the studied soil samples. Overall, P became less labile over time due to an increase in the Fe-P phase and a decrease in clay-P proportion; however, soil treated with higher water salinities had less clay-P, possibly due to low pH and elevated salt ion concentrations that hinder P re-adsorption from porewater onto clay minerals. In summary, our work demonstrates that increasing salinity associated with sea level rise can enhance soil P availability and release, potentially accelerating nutrient losses from saltwater-intruded agricultural soils, while also rendering soils unfavorable for cultivation as salts accumulate. Further studies should determine how these salinity-driven processes unfold under field conditions and long-term sea level rise, with implications for sustainable nutrient management in saltwater-intruded agricultural landscapes.

# Soil development on coal-waste dump in southern Poland

**Oimahmad Rahmonov[1], Agnieszka Czajka[*1]**

[1] *Department of Natural Sciences. Institute of Earth Sciences, Sosnowiec, Poland*

*agnieszka.czajka@us.edu.pl

**ABSTRACT**

The spontaneous succession of vegetation on waste heaps resulting from coal exploitation has long aroused the interest of researchers around the world because these are places where plant succession processes and soil development can be observed and monitored from the moment of initiation.

The objectives of this study were: (i) to determine the joint development of vegetation succession, (ii) to establish its influence on soil formation processes and soil characteristics against the background of environmental conditions, and (iii) to determine the chemical composition of plants as an element enriching soils with nutrients in the early stages of succession on a post-mining coal-waste heap.

The study was conducted at the mining waste dump of the Szczygłowice Coal Mine in southern Poland.

The floristic examinations consisted of an inventory of plant species growing on the analyzed area in divided surfaces. The course of vegetation succession in the area of the coal-waste heap was examined along a transect which ran from the newest areas of heaps with freshly dumped post-mining waste, through sodded areas, to the emerging initial forest with a dominant share of R. pseudacacia. Vegetation changes were analyzed both on the basis of satellite imagery and by a direct field survey, including an analysis of drone images.

Three soil profiles were produced under dominant plant communities representing particular stages of succession: initial - profile 1, optimal - profile 2, and terminal - profile 3. In the initial stage of succession under algocenoses 5 soil samples were also taken. Dried soil samples were and analyzed, following the standard procedures namely, pH measured potentiometrically in H2O and in 1N KCl using a glass electrode, total organic C (%) according to Tiurin's method, total nitrogen (Nt) content using the Kjeldahl method, and hydrolithic acidity (Hh) according to the Kappen method. Total phosphorus (Pt) was measured using the Bleck method, available phosphorus (Pavail) by Egner–Riehm's method and available Kavail and Mgavail.

The Spearman's rank correlation coefficient was applied to check whether there was any relationship between the concentrations of the selected elements in both plant materials, soil materials and crust with algae at the study profiles.

It was found that changes in the development of vegetation is closely related to the stages of coal waste disposal, where the initial, transitional, and terminal stages were distinguished. The organic carbon content in all samples is high. The highest content of total nitrogen was found in the algal crust and Olf and A levels in the initial forest. Notable contents of available elements were found in the algal shell. The algal crust serves as a good environment for soil formation, as the first stage. Plant succession is initiated by species with a wide ecological tolerance in the area studied.

# Salix acutifolia Willd. as an ecological engineer in the processes of soil formation and plant succession in sandy areas

**Oimahmad Rahmonov*[1], Anna Abramowicz[1], Agnieszka Czajka[1]**

[1] *Department of Natural Sciences. Institute of Earth Sciences, Sosnowiec, Poland*

*oimahmad.rahmonov@us.edu.pl

**ABSTRACT**

The processes of initiation of vegetation succession and soil development in the Błędowska Desert and other sandy ecosystems of the Silesian Upland are initiated mainly by the european violet willow *Salix acutifolia*, also known as the caspian willow. It is a pioneer species and is characterized by low habitat requirements. This species is the first to enter loose and bare sands after algae associations. In subsequent periods, as it develops, it increases its canopy and stabilizes the sand. This results in the systematic encroachment of herbaceous psammophilous species, especially *Pinus sylvestris*. The results show that nutrient accumulation is strongly associated with the canopy effect while nutrient accumulation is low or almost absent in the canopy gap spaces. Enriched zones under the canopy of *S. acutifolia*, reflecting the interaction of biotic and abiotic factors, are called fertility islands. The developing direct soil horizons in the canopy zone of willow vary in thickness depending on the distance from the trunk. The organic horizon and its sub-horizons create favourable conditions for the development and existence of soil organisms, which also affect the soil-forming process. Given the young age of the soil and the poor differentiation of soil horizons, the organic matter located directly above the mineral layer plays an important ecosystem role in the initial stages of vegetation succession and soil development. The quantity and quality of organic matter influences sorption capacity, degree of saturation with base cations and soil fertility. Broad-leaved species such as: *Salix acutifolia, Quercus robur or Betula pendula* positively influence the succession rate, causing the species diversifying through canopy effect.

The organic carbon content in all tested samples of *Salix acutifolia* ranges from 48.1 to 52.7%, with the highest concentration of this element found in fallen leaves. The concentration of total nitrogen in bark, fallen leaves and green leaves is 1.35%, 1.71% and 1.49%, respectively, and the C/N ratio in the tissues of these litter fractions ranges between 30 and 36. The nitrogen and phosphorus content is higher in fallen leaves than in green leaves.

Alkaline elements dominate in all organs, especially in the leaves. Hence, the pH of *S. acutifolia* leaves is less acidic than that of B. pendula. In the organic layer of the soil profile under *S. acutifolia*, aliphatic compounds dominate. Aromatic compounds also account for a significant proportion (9%). The predominance of aliphatic compounds in the humus layer is due to the poor mixing of organic matter with the mineral fraction, and organic compounds at this stage of soil succession in the humus layer originate primarily from the decomposition of dead roots of herbaceous plants and sharp-leaved willow shrubs. As communities become more complex and a distinct vertical structure develops, the proportion of lignin and polysaccharide derivatives increases.

## ABSTRACT

Ratios of radiogenic and metal(loid) stable isotopes are well-established tools in geosciences to trace geological transformation processes. Although these processes also occur in agricultural systems, the application of these isotope ratios in agriculture is still poorly constrained. Apart from the fact that the isotope composition of metal elements like iron (Fe) and magnesium (Mg) differ between soil compartments and plants, agricultural practices often alter biogeochemical processes and thus isotope ratios in agri-systems. Therefore, analyzing these stable isotopes can help understand the cycling and use efficiency of key nutrients under agricultural conditions. In this presentation, we will present several examples of such applications in the investigation of long-term agricultural land-use and sustainable subsoil management funded by the Deutsche Forschungsgemeinschaft (DFG, PaddyFe Project, No. 391749090) and the Bundesministerium für Forschung, Technologie und Raumfahrt (BMFTR, BonaRes-Projects Soil$^3$, No. 031B0026C, 031B0515C, and 031B1066C).

Using Fe stable isotopes we reconstructed Fe dynamics in a paddy chronosequence, revealing that long-term rice cropping and subsequent redox cycle altered the biological contribution in the terrestrial Fe cycle. Long-term liming reduced Fe availability to crops due to the increased soil pH and promoted the Fe uptake strategy of the crop through complexation of Fe(III) from the rhizosphere. Long-term liming also altered the exchangeable Mg pool of the soil and its Mg isotope composition by promoting Mg uptake.

Using metal stable isotopes in the assessment of sustainable subsoil management allowed us to explore the potential of subsoil amelioration through deep loosening and compost injection in optimizing nutrient and water use efficiency for crops. We first conceptually showed that Mg use efficiency of crops can be solely quantified from Mg stable isotope ratios when lime is not applied. We further used the radiogenic strontium isotope ratio ($^{87}Sr/^{86}Sr$) to reveal changes of the nutrient uptake depth caused by subsoil management. A shift in the $^{87}Sr/^{86}Sr$ ratio of crops indicated that deep loosening with compost incorporation in a silty Luvisol deepened the depth of nutrient uptake, whereas no such shift was observed in crops grown in a sandy Retisol. This suggests that when water is not a limiting factor subsoiling with compost incorporation is an effective management strategy to improve nutrient utilization from the subsoil, whereas under water-deficit conditions subsoil amelioration primarily improves water uptake from the subsoil but not nutrient acquisition.

We conclude that non-traditional metal stable isotopes are a powerful tool in agricultural sciences as they allow insights into biogeochemical cycling of nutrient elements.

# Mapping Microscale pH Dynamics at Soil–Amendment Interfaces Under Fluctuating Moisture Conditions

**ABSTRACT**

The incorporation of soil organic amendments creates decomposition hotspots, and the microscale variability of pH in soil-amendment hotspots is a critical driver of microbial activity and nutrient cycling. However, little is known about the pH dynamics at the soil–amendment interface, particularly under conditions of fluctuating moisture. In this study, we applied high-resolution planar optode imaging to monitor in situ microscale pH dynamics at the straw–soil interface in a typical fluvo-aquic soil during three consecutive drying–rewetting cycles. Two straw incorporation patterns—heterogeneous (patch) and homogeneous (uniform)—were compared to assess their effects on localized pH variations. The heterogeneous straw treatment induced pronounced acidification hotspots (pH < 6.6) concentrated around straw patches. During wetting, the acidic zones expanded radially outwards, accompanied by a progressive steepening of the pH gradient (up to 0.10 units $mm^{-1}$). Upon drying, water limitation caused these zones to contract inwards as the pH gradient flattened. In contrast, the homogeneous treatment exhibited dispersed, less intense acidification (pH 6.7–6.9) with smaller spatial and temporal fluctuations. Repeated drying–rewetting cycles promoted cyclic accumulation and depletion of formic and acetic acids at the straw–soil interface. The magnitude of both acidification and cation release ($Ca^{2+}$, $Mg^{2+}$, $K^{+}$) diminished across successive cycles, indicating the progressive depletion of labile straw components. These findings highlight the importance of straw spatial arrangement in shaping microscale soil acidification under moisture fluctuations, offering valuable insights for optimizing crop residue management and predicting soil biogeochemical responses.

*regitano@usp.br

**ABSTRACT**

Sulfamethoxazole (SMX) is an emerging contaminant commonly introduced into agricultural soils via manure and other organic amendments, where it can modulate microbial processes and contribute to the selection and dissemination of antimicrobial resistance genes. Its environmental persistence, transformation pathways, and ecological impacts, however, are strongly conditioned by land-use history, soil management practices, and the presence of co-occurring pollutants. This study investigated the dissipation of uniformly $^{13}$C-labeled SMX in parallel soils under three contrasting management systems: native forest, a soybean-maize rotation with limited cover-crop diversification, and a soybean system with a more diversified cover-crop mixture. For each soil, dissipation was assessed with and without polyethylene microplastics. Soils were amended with cattle manure spiked with $^{13}$C-SMX to achieve a final concentration of 442 µg kg$^{-1}$ and incubated for 42 days under controlled conditions (semi-dark room at 25 ± 2 °C). Polyethylene microplastics were incorporated at 0.14% (w/w), reflecting environmentally realistic levels in agricultural soils. Extractable $^{13}$C-SMX was quantified by LC-MS/MS using an optimized extraction protocol with high recovery and analytical sensitivity. SMX dissipation was very fast across all soils, with more than 70% loss within 7 days. Estimated half-lives ranged from 1.5 to 4.3 days, and microplastics only slightly increased dissipation rates. This rapid decline, faster than values commonly reported for temperate soils, likely reflects a combination of biotic and abiotic pathways: manure addition stimulated microbial co-metabolism, while Fe- and Al-rich mineral phases promoted sequestration of SMX-derived compounds into non-extractable residues. These results demonstrate that tropical soils can quickly attenuate sulfonamides, emphasizing that dissipation alone does not capture true degradability and must be interpreted separately from transformation and mineralization processes when evaluating antibiotic fate.

## ABSTRACT

Potassium (K) fertilisers, particularly muriate of potash (MOP) and sulphate of potash (SOP), are widely used to increase crop yield. However, interest in alternative K sources is rising due to the vulnerability of traditional K fertilisers to global trade disruptions. In this regard, polyhalite ($K_2SO_4 \cdot MgSO_4 \cdot 2CaSO_4 \cdot 2H_2O$) is a multi-nutrient mineral that also co-supplies calcium (Ca), magnesium (Mg), and sulphur (S), but the specific soil mechanisms and K release kinetics are poorly understood. To address this, we examined the nutrient release behaviour of polyhalite (POLY4® a granulated polyhalite product of Anglo American plc. (www.poly4.com)) in Australian highly weathered and calcareous loam soils, comparing its performance with SOP and MOP. Soils were incubated in Petri dishes with a fertiliser granule placed in the centre of the soil volume. Diffusive gradients in thin films (DGT) devices were then deployed to visualise and quantify, over time, the diffusion of potentially bioavailable K from the granules. The DGTs were analysed using X-ray fluorescence microscopy (XFM). After 56 days (d), incubated soils were sampled in four concentric rings of increasing distance away from the fertiliser granule and analysed for i) pH and electrical conductivity ii) nutrient fractions using sequential extraction and iii) potassium speciation using X-ray absorption spectroscopy (XAS). The K diffusion from MOP and SOP was faster than POLY4® after 3 d of incubation. However, after 7 d, SOP and POLY4® showed similar K diffusion, and between 14 to 56 d, all K sources exhibited comparable K diffusion distances. After incubation, some of the added Ca and S from POLY4® remained in the granule. In both soils at the fertiliser zone (0-1cm), while K forms from POLY4® were largely water-extractable, the majority of K forms from SOP and MOP were in the ammonium acetate extractable fraction. Additionally, Ca, Mg, and S forms in POLY4® were water-extractable forms at the fertiliser zone. These findings suggest that POLY4® acts as slow-release fertiliser, where its K release remains water soluble and less soil sorbed than when SOP or MOP are used.

**ABSTRACT**

Contamination of food crops by metals and metalloids (hereafter metals) poses increasing food safety risks. Both essential and toxic metals accumulate in crops and influence nutrition and human health, which necessitates the research on the plant metallome (the full composition of metals in plants). Nonetheless, how metallome profiles of different plant tissues change under variable soil wetting-drying periods and across growth stages remains poorly understood. This study investigated metal uptake, accumulation, and translocation in carrot (*Daucus carota* subsp. *sativus*) and wheat (*Triticum aestivum* L.) across growth stages under different soil wetting–drying regimes in a greenhouse experiment.

Both carrot and wheat were grown in a sandy soil with alternating dry (D) and wet (W) periods capped at soil water holding capacity of 35% or 80%. For carrot, the five growth stages were grouped into three phases, resulting in treatments (i.e., DDW, WDD, and WWW). Wheat growth was divided at Feekes 9 into two phases, resulting in three treatments (i.e., DW, WD, and WW). At the end of each growth stage of carrot and five selected Feekes stages of wheat, plant and soil samples were collected for each treatment in triplicates. The elemental analyses were performed by inductively coupled plasma – mass spectrometry (ICP–MS) after digestion following EPA 3051A method.

Multiple statistical analyses showed that plant growth stage was the primary determinant of metallome profiles in both carrot and wheat, with minimal influence from soil water conditions (except in wheat kernels). Hierarchical clustering of metal accumulation in aboveground tissues indicated that the clustering patterns were mainly driven by growth stage, while roots were less affected. ANOSIM and PCA confirmed that growth stage predominantly shaped metallomes in plant tissues, with limited impact from soil water conditions. However, wheat kernels showed different metal compositions among soil water treatments. Community analyses further revealed temporal changes in diversity and evenness, and distinct metal co-occurrence networks in different tissues based on Spearman correlation coefficients among metals. Translocation factors from roots to aboveground parts and bioconcentration factors highlighted dynamic changes in metal mobility across plant developmental stages and soil water conditions. Our ongoing work is exploring molecular mechanisms underlying crop metallomes using transcriptomic and metabolomic approaches.

# Process-Based Multi-Surface Modeling of Soil Arsenic: Enabling Large-Scale prediction of environmental fate and Guiding Remediation Strategies

**Yuhong Huang[1*], Xueyuan Gu[1]**

[1] *State Key Laboratory of Water Pollution Control and Green Resource Recycling, School of Environment, Nanjing University, Nanjing, P.R. China*

*yhhuang@smail.nju.edu.cn

**ABSTRACT**

Accurate speciation analysis of inorganic arsenic (As) in soils is essential for predicting its environmental fate and transport. However, commonly used sequential extraction and advanced spectroscopic techniques suffer from substantial limitations: the former is labor-intensive, and the latter requires sophisticated instruments, making both unsuitable for high-throughput analyses. Our study aims to develop a process-based, multi-surface speciation model of As to enable high-throughput, broad-coverage prediction of As speciation in complex soil environments. In previous work, we identified and constructed surface speciation models of As on the surfaces of iron oxides [1] and clay minerals [2] based on microscopic interfacial mechanisms, while also quantifying the effects of coexisting cations and anions on As adsorption. Here, we further integrate multiple processes, interfaces, and ions to build a comprehensive multi-surface As speciation model (*Figure 1*). We particularly focus on identifying model-sensitive parameters and quantifying predictive uncertainties, aiming to pinpoint the key soil physicochemical properties that control As environmental behavior, minimize model parameterization, and maintain an acceptable error range. By combining this model with global soil databases, we are able to generate high-resolution, speciation-informed maps of As at the global scale. Overall, our study provides a robust and accurate tool for forecasting As behavior and fate in soils, highlights a bottom-up research paradigm linking microscopic speciation to macroscopic behavior, and ultimately offers valuable guidance for soil As remediation.

# Chemical transformation pathways demonstrating elemental sulfur effectiveness in alkaline-sodic soils

**Mst Sarmin Akter Ranu[1*], Bernhard Wehr[1], Ram C. Dalal[1] and Yash Pal Dang[1]**

[1] *School of Agriculture and Food Sustainability, The University of Queensland, St Lucia, Queensland 4072, Australia*

* m.ranu@uq.edu.au

**ABSTRACT**

Elemental sulfur ($S^0$) is commonly used to improve alkaline–sodic soils, although its effectiveness can vary depending on soil physicochemical characteristics. We conducted a 60-week incubation study at 25 °C and 50% plant-available water content (PAWC) using six highly alkaline–sodic soils from Queensland (pH 9.0–10.0) to evaluate the remediation potential of $S^0$. Three sulfur sources—micronised sublimed sulfur, DEVCO sulfur-bentonite, and SWANCORP sulfur-bentonite—were applied at six rates (0, 0.25, 0.5, 1.0, 1.5, and 2.0 t $ha^{-1}$). Proton concentration, electrical conductivity (EC), and sulfate-sulfur ($SO_4$-S) concentration were measured at 0, 6, 12, 24, 40, and 60 weeks to track sulfur oxidation and associated changes in soil chemistry. Elemental sulfur application increased proton concentration by 20–50-fold, raised EC from approximately 0.3–0.9 to 4–5 dS $m^{-1}$, and increased $SO_4$-S concentration from 7–60 to 90–130 mg $kg^{-1}$ (a 2–20-fold increase), demonstrating substantial sulfur oxidation and the accumulation of sulfate and soluble reaction products. These coordinated increases indicate that $S^0$ effectively drives chemical transformations required for ameliorating alkaline–sodic soils. Overall, application rates of 1.0–2.0 t $ha^{-1}$ produced the strongest improvements while remaining within acceptable salinity thresholds. Our results provide soil-specific guidance for optimising elemental sulfur use in the reclamation of alkaline–sodic soils, aligning with previous findings that elemental sulfur improves soil chemical properties, as demonstrated by Akay et al. (2019).

# Persistence, Transport and Transformation of Per- and Polyfluoroalkyl Substances in Soils from repeated Land Application of Biosolids

**Zhiliang Xu [1*], Qianqian Dong [1], Qinyuan Cao [1], Jim Ippolito [2], Wei Zhang [1], and Hui Li [1]**

*xuzhilia@msu.edu

**ABSTRACT**

A large portion of biosolids generated from wastewater treatment plants are applied to agricultural land for their plant nutrient values and as soil amendment to improve soil health. Many biosolids contain elevated levels of emerging pollutants, especially per- and polyfluoroalkyl substances (PFAS). The repeated land applications of biosolids could lead to increasing PFAS accumulation in soil and leaching down to groundwater. In this study, we collected soil samples at soil profile depths down to 180 cm and corn/wheat grains produced at the site which have received the repeated land application of biosolids for > 20 years. In this study, we applied the EPA 1633 analytical method targeting 43 PFAS in soils and grains collected in 1999, 2006, 2012 and 2018. Twenty out of 43 targeted compounds were identified and quantified at the levels of micrograms per kilogram of soil, which included legacy PFAS (e.g., perfluoroalkyl carboxylic acids and perfluoroalkyl sulfonic acids) and PFAS precursors (e.g., polyfluoroalkyl phosphate dieasters and perfluorooctane sulfonamidoacetic acids). Both long- and short-chain PFAS could migrate downwards to deep soil profiles but to varying extents, with the latter group transport deeper in soil profiles. The smallest-sized PFAS targeted in this study, perfluorobutane sulfonic acid (PFBS), was found to leach down even to the depth of 180 cm at one plot, indicating short-chain PFAS have a very high mobility and could contaminate the larger areas of agricultural land. The positive relationship was found between the total mass of PFOA and PFOS in soil profiles versus the cumulative loading rate of biosolids, indicating the continuous inputs of these two legacy PFAS compounds from the land-applied biosolids. The long-term repeated land applications of biosolids might result in the increased abundance of new PFAS in the soil with years such as PFBS, which could be due to the shifting PFAS composition in biosolids or the transformation of precursors with a long time.

**ABSTRACT**

*Coffea arabica* L. is a vital economic crop in the highland regions of Northern Thailand, but its sustainable production is increasingly threatened by soil degradation and climate change. This study aimed to assess the long-term efficacy of corn cob biochar application on critical soil parameters. We evaluated the effects on soil physical and chemical properties and the nitrogen (N) cycle by comparing the control to biochar application 12 months prior. The results indicated that biochar application significantly enhanced soil quality. Specifically, soil organic matter (SOM) increased by 5.35% compared to the control. The electrical conductivity (EC) reached a maximum of 74.0 ± 1.31 mg $kg^{-1}$ in the biochar application. Crucially, biochar improved exchangeable Potassium increased from 378.75 ± 7.25 mg $kg^{-1}$ in the control to 647.25 ± 1.87 mg $kg^{-1}$ in the biochar application, and exchangeable Magnesium was significantly higher in the biochar application (140.25 ± 0.53 mg $kg^{-1}$) compared to the control (49.20 ± 1.26 mg $kg^{-1}$). Regarding the N cycle, ammonium ($NH^{4+}$) levels were highest in the biochar application (51.12 ± 0.63 mg $kg^{-1}$), but were not significantly different from the control. However, the biochar application showed the highest nitrate ($NO_3^-$) level, reaching 114.54 ± 9.61 mg $kg^{-1}$. The results demonstrate biochar's potential as an effective and sustainable soil management strategy to enhance productivity and resilience for *Coffea arabica* L. production in vulnerable highland ecosystems.

**ABSTRACT**

Mitigating arsenic (As) contamination, a toxic metalloid, through magnetite adsorption is a promising remediation strategy. However, the effects of Fe(II) and organic acid release from rice roots on As sorption on magnetite are not fully understood. Herein, we investigated the effects of Fe(II) and acetic acid, as a model organic acid released from rice roots, on As(V) and As(III) sorption on magnetite. Kinetic results demonstrated that Fe(II) with or without acetic acid promoted a complete As(V) adsorption. Conversely, acetic acid alone lowered As(V) adsorption compared to the addition of Fe(II) or Fe(II) + acetic acid. Similar trends were observed in As(III) systems, where As(III) adsorption decreased, but oxidation of As(III) to As(V) increased. Our findings highlight the combined effects of Fe(II) and organic acids on As-magnetite interactions, with implications for As mobility at the soil-rice root interface under redox conditions.

# Quantifying drivers of soil acidification under pakchoi cultivation with varying nitrogen inputs in Hainan, tropical China

**Zhu Yingying[1,2], Nan Xuan[1,2,3], Jiang Jun[1], and Hong Zhineng[1*]**

*[1] State Key Laboratory of Soil and Sustainable Agriculture, Institute of Soil Science, Chinese Academy of Sciences, Nanjing, China*

**ABSTRACT**

Soil acidification poses a significant challenge to global agricultural sustainability. In China, particularly in tropical regions like Hainan, soil acidification has worsened over recent decades, threatening crop productivity and ecosystem stability. However, the mechanisms driving soil acidification in this area remain poorly quantified.

This study employed a soil column-pot experiment based on the proton budget method to quantify the contributions of various acidification processes (N cycling, unbalanced crop uptake of anions and cations (crop uptake), direct proton input, mineral weathering/cation exchange, and anion desorption) in three typical soils in Hainan including volcanic latosol (WC), granite latosol (JA), alluvial paddy soil (JJ). Each soil was subjected to varying nitrogen levels (0, N0; 200 kg N $ha^{-1}$, N1) under pakchoi (*Brassica rapa*) cultivation.

The results (Figure 1) revealed that anion desorption was the dominant proton source (70%-90%) in the two latosols (WC and JA), while it contributed equally with crop uptake (45%-54%) in the paddy soil (JJ). The contribution of direct proton input was negligible (<0.1%). Mineral weathering and cation exchange were the primary buffering mechanisms, neutralizing 78–99% of generated protons across all treatments. Nitrogen transformation contributed to proton consumption in some treatments, particularly in WC-N1, where it accounted for 21%. Proton production and consumption were significantly influenced by soil type ($P< 0.01$), with JJ and JA soils showing higher proton flux compared to WC soil. Nitrogen fertilization significantly increased proton production and consumption in WC and JJ soils (P = 0.04 and P = 0.02, respectively), but had no significant effect on JA soil.

This study underscores that anion desorption and plant uptake, not N transformation, are the predominant acidification pathways in tropical vegetable systems in Hainan. These findings offer valuable insights for developing tailored soil management strategies to mitigate acidification in tropical agricultural systems.

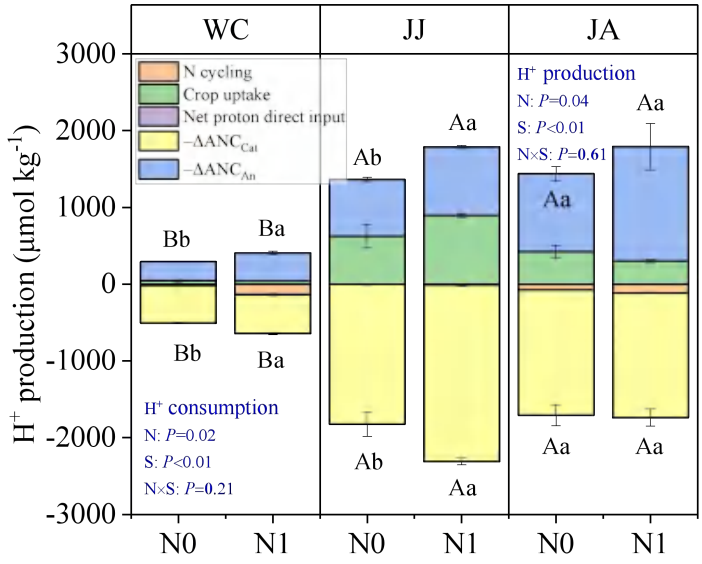

**Figure 1** Proton production/consumption under different treatments by different processes including nitrogen transformation (N Cycling), unbalanced crop uptake of anions and cations (crop uptake), net proton direct input, mineral weathering/cation exchange (-$\Delta ANC_{Cat}$), and anion desorption (-$\Delta ANC_{An}$). Positive and negative values indicate proton production and consumption, respectively. WC, JJ, and JA represent the three soils, and N0 and N1 indicate the treatments without nitrogen fertilizer and conventional nitrogen fertilization (200 kg N $ha^{-1}$), respectively. Uppercase and lowercase letters represent significant differences ($P< 0.05$) in proton production and consumption among different soil types and nitrogen application levels, respectively. Error bars indicate the standard error (SE, n = 3).

# Abiotic Transformation of PFAA Precursors in Soil Under Environmental Conditions

**Ayush Pokharel[1], Tanvir Siddike Moin[1], and Jianzhou He[1,2,3,*]**

*[1] Department of Biochemistry, Chemistry and Physics, [2] Center for Advanced Materials Science, [3] James H. Oliver Jr. Institute for Coastal Plain Science, Georgia Southern University, Savannah, GA 31419*

**ABSTRACT**

Per- and polyfluoroalkyl substances (PFAS) remain a major environmental concern due to their persistence and the continuous discovery of new precursor compounds in soil systems. While biotic pathways have been studied extensively, the role of soils in driving abiotic transformation of perfluoroalkyl acid (PFAA) precursors under environmentally relevant conditions is far less understood. This study investigates how common soil components—minerals, natural organic matter, redox-active species, and moisture regimes—facilitate or inhibit the chemical transformation of several representative precursors. The goal is to clarify the extent to which soils themselves act as reactive media capable of generating terminal PFAAs.

We conducted controlled laboratory experiments using well-characterized soils spanning a range of textures, organic carbon contents, and redox potentials. Precursors, including fluorotelomer sulfonates and polyfluorinated amides, were incubated under conditions that mimic moistures, wet-drying cycles, natural pH gradients, and oxygen-limited microenvironments. Over weeks to months, transformation products were quantified using high-resolution mass spectrometry. Reaction kinetics were evaluated alongside changes in soil physicochemical properties to identify key drivers of abiotic conversion.

We speculate that soil can promote slow but measurable transformation and degradation of precursors into shorter-chain PFAAs. Mineral surfaces-especially iron- and manganese-bearing phases-played a central role. These minerals participated in redox-mediated processes that altered precursor functional groups, resulting in stepwise defluorination or oxidation. Organic matter contributed both catalytically and through sorption-driven concentration of precursors at reactive interfaces. Moisture fluctuations were also crucial; periods of drying and rewetting produced transient chemical conditions that accelerated transformation in several soil types. However, transformation rates varied widely, underscoring the heterogeneity of real-world soils.

The study provides new evidence that abiotic processes in soils contribute to the environmental formation of persistent PFAAs. Although slower than microbial pathways, these reactions may operate continuously across large soil volumes and long timescales. As a result, abiotic transformation likely represents a non-negligible source of PFAA accumulation in terrestrial environments. Understanding these mechanisms is essential for improving fate models, assessing long-term risks, and designing more effective remediation strategies for PFAS-impacted sites.

# Molecular modeling of natural organic matter-heavy metal cations interactions

**Chi Zhang*, Zhiyu Zhou, and Hanzhong Jia**

*College of Natural Resources and Environment, Northwest A & F University, Yangling, Shaanxi, 712100, P.R. China*

**ABSTRACT**

Interaction between natural organic matters (NOM) and heavy metal cations in aqueous environment are of great significance for maintaining stability of organic carbon and restraining transport of heavy metal contaminants in (bio)geochemical processes. We systematically explore the aggregation process and complexation between NOM and heavy metal cations ($Ag^{+}$, $Cd^{2+}$, $Pb^{2+}$, $Zn^{2+}$, $Eu^{3+}$) under different pH condition by molecular dynamics (MD) simulations, umbrella sampling method, and quantum chemistry calculations. The character of molecular structures NOM-heavy metal complexes and association are quantified. In acidic pH condition, aggregation proceeds via H-bonding and π-π interactions between NOM fragments. In neutral condition, $Ag^{+}$, $Cd^{2+}$, $Pb^{2+}$, and $Eu^{3+}$ can form inner-sphere complexes with the surface carboxylic groups and therefore reduce intermolecular charge repulsion, eventually leading to NOM aggregation, and it shows that even without direct binding, the outer-sphere adsorbed $Zn^{2+}$ can also result in the formation of NOM assemble through H-bonding. Consequently, these heavy metals are capable of promoting NOM aggregation regardless of the complexing ways. Complexing free energy calculations characterized the dynamic processes of cations binding to the carboxylic groups of NOM fragment and the related energy landscape. This study provides quantitative insights for understanding the environmental processes of heavy metals and cycle of C in aquatic ecosystem, and contributes to developing environment-friendly strategies for controlling heavy metal contaminants.

**ABSTRACT**

Colloidal particles, the finest constituents of soil, originate from complex physicochemical interactions among clay minerals, metal oxides, and organic matter. Their environmental behavior plays a critical role in soil structure formation, solute transport, and soil genesis. As particle size decreases, changes occur in the composition of organic matter and clay minerals, as well as in surface properties and aggregation-migration behaviors. However, studies addressing the size-dependent surface characteristics and environmental behaviors of soil colloids remain limited. In this study, typical zonal soils from China—Phaeozem (black soil), Cambisol (brown soil), Luvisol (yellow-brown earth), and Ferralsol (latosol)—were selected. Colloidal fractions with diameters of $d$ < 2000 nm, $d$ < 1000 nm, $d$ < 500 nm, and $d$ < 100 nm were extracted through ultrasonic dispersion combined with high-speed centrifugation, and their composition, surface properties, and aggregation/migration behaviors were systematically analyzed. The results showed that, as particle size decreased, colloidal particles from Phaeozem, Cambisol, and Luvisol exhibited reductions in both diameter and thickness, while Ferralsol colloids showed minimal changes. The absolute value of the zeta potential initially increased and then decreased, indicating reduced surface charge variability. Soil organic carbon was predominantly enriched in finer fractions, particularly in nanocolloids ($d$ < 100 nm), which were characterized by a higher density of surface functional groups, greater aromaticity, and lower hydrophilicity. The critical coagulation concentration (CCC) of Phaeozem colloids decreased with decreasing particle size, while Cambisol colloids exhibited an initial decrease followed by an increase. In contrast, the CCC of Luvisol and Ferralsol colloids increased as particle size decreased. These variations in aggregation behavior were attributed to the balance between electrostatic repulsion and van der Waals attraction. The highest mobility was observed for the $d$ < 500 nm fractions of Phaeozem, Cambisol, and Luvisol colloids, and for the $d$ < 1000 nm fraction of Ferralsol colloids. Conversely, the weakest mobility was found in the nanocolloidal fractions of all soils, likely due to their lower absolute value of the zeta potential and higher densities of surface functional groups. The critical particle diameters controlling size effects were determined to be 500 nm for Phaeozem, Cambisol, and Luvisol colloids, and 1000 nm for Ferralsol colloids. These findings provide a theoretical foundation for more accurately assessing the environmental behavior of soil colloids and their roles in pollutant transport processes.

**Key words:** Soil colloids; Size-dependent behavior; Critical coagulation concentration; Mobility;

# Soil–Plant Isotopic Coupling in Support of PDO Agri-Food Traceability

**R. Ofano[1*], D. Potočnik[2], N. Ogrinc[2], P. Adamo[1*]**

[1]Department of Agricultural Sciences, University of Naples Federico II, Portici (Naples), Italy

[2]Jožef Stefan Institute, Department of Environmental Sciences, Ljubljana, Slovenia

paola.adamo@unina.it

**ABSTRACT**

Authentication and geographical traceability are essential to protect the quality and integrity of agri-food products with geographical indications. Stable isotope ratio analysis provides intrinsic markers of origin that reflect environmental conditions and agronomic practices during plant growth, offering a robust alternative to documentary traceability. The isotopic composition of light bioelements—carbon ($\delta^{13}C$), nitrogen ($\delta^{15}N$), and sulfur ($\delta^{34}S$)—captures soil–plant–atmosphere interactions and has proven effective in food authentication, although its application to tomato provenance remains limited.

This study investigates the potential of $\delta^{13}C$, $\delta^{15}N$, and $\delta^{34}S$ as tracers for the authentication and geographical discrimination of *Pomodorino del Piennolo del Vesuvio* (PPV) PDO. Tomato fruits and corresponding soils were collected over four growing seasons from farms located within and outside the PDO area and analysed by isotope ratio mass spectrometry (IRMS). Spatial and interannual variability were evaluated, and chemometric approaches were applied to assess discrimination performance.

Across the four years, interannual isotopic variability was limited and did not obscure the geographical signal. $\delta^{13}C$ values, consistent with $C_3$ plant physiology, showed moderate year-to-year variations mainly related to water availability, while $\delta^{15}N$ remained relatively stable. $\delta^{34}S$ displayed a progressive enrichment over time without compromising area discrimination. PDO tomatoes were characterized by higher $\delta^{13}C$ values, reflecting drier pedoclimatic conditions and rainfed cultivation on Vesuvian slopes, whereas non-PDO samples showed higher $\delta^{15}N$ and $\delta^{34}S$ values, likely linked to different fertilization practices and sulphur sources. Significant differences were also observed in elemental composition (C, N, S).

Multivariate analyses confirmed a clear separation between PDO and non-PDO samples. Principal Component Analysis highlighted $\delta^{15}N$ and $\delta^{34}S$ as primary discriminants, while Linear Discriminant Analysis achieved classification accuracies between 85% and 100% depending on the year, and approximately 84% for the combined dataset. No significant isotopic or elemental differences were found between PPV varieties, indicating that environmental and management factors outweigh genotypic effects. Soil isotopic data mirrored fruit signatures, and significant correlations between soil and tomato isotopic values further supported the soil–plant isotopic coupling.

Overall, the combined use of $\delta^{13}C$, $\delta^{15}N$, and $\delta^{34}S$, integrated with chemometric tools and soil characterization, provides a robust and science-based framework for PDO agri-food traceability and the authentication of Vesuvian tomatoes.

*juhasz.evelin@agr.unideb.hu

## ABSTRACT

Phosphogypsum (PG), a low-cost by-product of the phosphate fertilizer industry, has received growing attention, particularly in regions with degraded soils. Despite its potential benefits, PG poses substantial environmental challenges due to its large-scale accumulation: around 7 billion tons have been stockpiled globally, although 80 million tons are produced annually and only 15–40% is currently utilized. PG can improve soil health by regulating pH, stabilizing aluminum compounds and enhancing soil structure. Additionally, it contains essential nutrients such as calcium, sulfur and phosphorus, making it a promising soil amendment and fertilizer.

This study evaluated the effects of PG application on soil chemical properties, nutrient availability, and heavy metal mobility in saline soil cultivated with spring wheat (*Triticum aestivum* L.). A two-year pot experiment was conducted under controlled greenhouse conditions. In the first year, PG was applied at rates of 2 and 10 t $ha^{-1}$. In the second year, residual effects were assessed without additional PG, while a separate set of pots received repeated applications at the same rates to evaluate cumulative impacts. Although the experiment spanned two years, the study focuses on the results from the second year. Soil samples were analyzed for toxic elements and heavy metals, including aluminum (Al), arsenic (As), barium (Ba), chromium (Cr), cobalt (Co), lead (Pb), and cadmium (Cd), as well as for essential nutrients (phosphorus (P), potassium (K), calcium (Ca), magnesium (Mg), sulfur (S) and sodium (Na)).

Residual effects of PG generally resulted in higher concentrations of Al, Ba, Cr, Co, Pb, and Cd than repeated applications, especially at 10 t $ha^{-1}$. Repeated applications produced mixed effects on these elements, occasionally reducing their levels to the control. As showed no response to both residual and repeated PG applications.

PG increased P, Ca, Mg, and S levels compared to the control, with higher doses producing more pronounced effects. Residual treatments mainly enhanced P and Mg availability, reflecting the slow release of phosphate and mobilization of native Mg. In contrast, repeated applications had a stronger effect on Ca accumulation, due to the cumulative addition of Ca. Sulfur enrichment occurred in both application types, owing to the sulfate content of PG. Sodium concentrations decreased under all PG treatments, likely through $Ca^{2+}$ displacement of $Na^{+}$ from exchange sites, indicating a potential ameliorative effect on saline soils.

Overall, PG improved nutrient availability while repeated applications tended to limit heavy-metal accumulation compared to residual effects, indicating that controlled, repeated PG use may enhance soil quality with lower environmental risk.

**ABSTRACT**

Salinized arid regions harbor substantial yet fragile carbon pools and are experiencing multiple disturbances from intensive reclamation. Here we evaluate the response of iron-bound organic carbon (Fe-bound OC) to salinization and reclamation across a 1600-km transect in northwest China. Fe-bound OC averages 16.6% of soil organic carbon (SOC) in salt-affected natural vegetation areas but decreases with increasing salinity. Crystalline iron mineral phases, dominant in these areas, stabilize aromatic organic compounds through adsorption, with a shift to coprecipitation-dominated mechanisms post reclamation. Although reclamation increases Fe-bound OC and SOC contents, the limited availability of iron constrains iron-carbon coupling, resulting in a reduced Fe-bound OC contribution to SOC (12.7%). This finding highlights the potential to enhance net carbon sequestration during reclamation by strategically managing iron-carbon coupling. The complementary incubation experiments demonstrate that the tailored application of crystalline iron (oxyhydr) oxides offers a promising pathway to synergize carbon sink enhancement with agricultural productivity in salinized arid regions, thereby advancing climate-resilient land restoration.

## ABSTRACT

Organic amendments are applied to agricultural soils to maintain fertility and function. In the present study, we monitored the CO2 emissions and analyzed the microbial biomass, community structure, and network complexity under single and combined applications of maize straw and maize straw-derived biochar (550 °C, 2 h) during a 180-day incubation experiment. The cumulative $CO_2$ emissions were ordered straw > biochar + straw > biochar, and the $CO_2$ emissions in the biochar + straw treatment were 41%–51% lower than those of the straw-only treatment. The content of phospholipid fatty acids (PLFAs) was not affected by biochar but increased under straw ($p < 0.05$) and decreased by 1.9%–46% under the combined treatment compared with the straw-only treatment, suggesting that microorganisms had various demands for nutrients. The greatest effects of applying organic material on the microbial community were found at the end of incubation under biochar, but at the start of incubation under straw addition, based on the nutrient supply provided by the type of material input. Biochar + straw strengthened cooperation between microorganisms by enhancing network complexity and alleviating competition in the network structure. Therefore, biochar + straw had an optimized effect on mitigating CO2 emissions and stimulating microbial community development compared to straw-only.

## ABSTRACT

**Purpose**

Saline acid sulfate soil is a type of acid sulfate soil affected by seawater intrusion, characterized by both acid sulfate properties and salinity. This soil contains high concentrations of sulfides, which, upon oxidation, form sulfuric acid, further increasing acidity and releasing toxic elements such as aluminum (Al) and iron (Fe) into the soil solution. This study aims to utilize amendments such as lime (LM), cow manure (CM), husk biochar (HB), and their combinations to reduce Al fractions, thereby transforming them into more stable forms to mitigate soil toxicity for enhancing agricultural sustainability in these degraded environments.

**Methods**

A greenhouse incubation experiment was established with six treatments: control (no amendment), LM, CM, HB, HB+LM, and HB+CM applied under two water regimes (submerged and moist at 60% field capacity), each with four replications. Soil samples were analyzed for aluminum fractions using the single extraction method. The aluminum fractions include: Exchangeable aluminum ($Al_K$), Weakly organic-bound aluminum ($Al_{Cu}$), Strongly organic-bound aluminum ($Al_p$), Non-crystalline aluminum ($Al_o$), Crystalline aluminum ($Al_n$), Crystallizes tightly aluminum ($Al_n$-$Al_o$).

**Results**

In the submerged condition, $Al_{Cu}$ was highest in HB+CM (64.36 mg $kg^{-1}$) and lowest in HB+LM (49.93 mg $kg^{-1}$). $Al_p$ was greatest in the CM treatment (4,877 mg $kg^{-1}$) and lowest in HB+LM (4,414 mg $kg^{-1}$), indicating a strong Al-fixation capacity of CM under submerged conditions. $Al_o$ increased markedly in HB+LM (161.01 mg $kg^{-1}$). $Al_n$ and $Al_n$-$Al_o$ did not differ significantly among treatments. $Al_K$ was lowest in HB+LM (9.91 mg $kg^{-1}$) and highest in CM (17.42 mg $kg^{-1}$), demonstrating that LM, particularly when combined with HB, effectively reduced $Al_K$. Moist condition, $Al_o$ remained highest in HB+LM (175.38 mg $kg^{-1}$). $Al_K$ decreased with HB+LM (15.58 mg $kg^{-1}$), whereas the control maintained higher values. $Al_n$-$Al_o$ remained stable and was not affected by the amendments. Overall, submerged conditions amplified the differences among amendments, whereas at moist conditions, the HB+LM was particularly effective in increasing $Al_o$ and reducing $Al_K$.

**Conclusions**

The use of soil amendments such as LM, CM, HB, and their combinations (HB+LM and HB+MC) has proven effective in reducing the levels of $Al_K$ and $Al_{Cu}$. These amendments not only increase soil pH, promoting the precipitation of aluminum into insoluble forms, but also create organic bonds that transform aluminum ($Al_K$, $Al_{Cu}$, and $Al_p$) from more easily absorbed forms into less toxic forms such as $Al_o$ and $Al_n$. As a result, the toxicity of Saline acid sulfate soil is minimized, creating favorable conditions for plant growth.

# Sorption and Desorption of Phosphorus in Soil: Implications for Water Quality

**Jian Liu[1*], and Karin Blombäck[2]**

*[1] Department of Soil and Land Use, Norwegian Institute of Bioeconomy Research, Ås, Norway)*

*[2] Department of Soil and Environment, Swedish University of Agricultural Sciences, Uppsala, Sweden)*

*jian.liu@nibio.no

**ABSTRACT**

In Norway, many agricultural soils are enriched in phosphorus (P), raising concerns about water quality. This issue is particularly pronounced on animal farms, where repeated manure applications have resulted in substantial soil P accumulation. Laboratory experiments conducted on a range of soils showed that leaching of dissolved P is strongly influenced by soil P sorption and desorption properties. In particular, the mass-weighted, whole-profile degree of P saturation determined using the ammonium lactate extraction method (DPS-AL) was found to be an excellent predictor of the flow-weighted mean concentration of total dissolved P (FWMC-TDP) (adjusted $R^2 = 0.93$, $p < 0.001$) (Liu et al., 2024). This strong relationship has important implications for assessing the risk of P leaching.

Within the EU Horizon-funded SOILPROM project, we aim to integrate this relationship into P modeling using the ICECREAM model. The modeling is based on a long-term monitored field site in southeastern Norway, where climate data and field management information have been collected since 1992, and P losses via both surface runoff and subsurface drainage were measured during 1992–2005. These long-term datasets provide a robust foundation for model calibration, validation, and predictive simulations. Results from both the laboratory experiments and the model simulations will be presented at the conference.

**ABSTRACT**

Soils contain the largest pool of terrestrial carbon, and thus significantly influence climate change either by releasing $CO_2$ under industrial cropping, or by sequestrating carbon with conservation practices, yet the role of urban soils in the global carbon cycle is poorly known. Since urban areas contribute over 70% of global greenhouse gas emissions due to dense, anthropogenic pollutant-emitting activities (UN-Habitat, 2011), we hypothesized that the physico-chemical properties of soils could be altered by higher atmospheric $CO_2$ concentrations. There is also a lack of high-resolution urban maps of soil pH, because published literature reports only estimations based on digital modeling with few real data (Suleymanov *et al.*, 2025). Here, we studied the pH of 192 soils sampled near the city center in three block of increasing urbanization, and in natural surroundings of Xi'an, a megacity of 9.2 millions inhabitants. We also measured atmospheric $CO_2$ levels. Results show statistically significant soil pH differences with degrees of urbanization and pollution, suggesting $CO_2$-induced soil acidification. We also present the first high-resolution (50 m) map of soil pH in a megacity.

**ABSTRACT**

The acceleration of global warming is calling for reducing fossil $CO_2$ emissions, yet the sources and spatial distribution of $CO_2$ are still poorly known, notably in urban areas, which contribute over 70% of global greenhouse gas emissions due to dense, anthropogenic pollutant-emitting activities (UN-Habitat, 2011). While the occurrence of $CO_2$ domes have been evidenced at the whole city scale (Idso et al. 2013), the long-term distribution of atmospheric $CO_2$ levels at block and road scales remains unknown. In particular, it is not known whether fossil $CO_2$ is homogeneously mixed by the traffic-induced city local winds, or remains concentrated in some specific urban areas. Here we studied one year of local fossil $CO_2$ pollution by analyzing the 374 samples of plant leaves from four species, taken at 50 m distance in three Xi'an blocks, and in natural areas as control. Fossil fuel carbon was distinguished using bulk and molecular $^{13}C$ analysis (Lichtfouse and Eglinton, 1995, Lichtfouse et al. 2003), and we modeled city winds at the local scale. Results show striking differences in fossil carbon ratio with the occurrence of '$CO_2$ islands', proving that $CO_2$ is not homogeneously mixed by city winds, suggesting protective effects of urban vegetation, e.g. trees, and of urban infrastructure, e.g. 30-stories buildings. Molecular isotope analysis allowed to exclude the possible contribution of airborne fossil fuel hydrocarbons, which is supported by the high combustion efficiency of actual vehicle engines and by the fast increase of the number of electric vehicles. Overall, these findings represent the first high resolution map of fossil carbon pollution in a city.

**ABSTRACT**

Reactive oxygen species (ROS) are critical agents driving elemental biogeochemical cycles and the transformation of pollutants in Earth's surface environments. Conventionally, abiotic ROS generation has been predominantly attributed to photochemical reactions and transition metal-catalyzed Fenton-like processes. Recently, growing attention has been paid to contact electrification at water-solid interfaces and its role in initiating physicochemical processes. Electron transfer during water-solid contact can drive chemical reactions, a mechanism known as contact-electro-catalysis (CEC). As a novel catalytic process powered by mechanical energy, CEC has been demonstrated to effectively generate ROS at solid-liquid interfaces. However, its significance and mechanisms in natural settings involving key reactive minerals, such as iron oxides, remain poorly understood. This study investigated the possibility and mechanistic pathways of ROS production via CEC at the interface between iron minerals and water. Our experimental results confirmed that contact electrification occurred between iron minerals and water with further indeed induced ROS generation. Notably, unlike the CEC pathways reported for polymeric materials, we discovered that ROS generation in this mineral system proceeded primarily through a synergistic mechanism. This mechanism involved an initial CEC step that subsequently activates and couples with surface Fenton-like reactions on the mineral. In this process, surface functional groups of iron minerals are pivotal in governing this interfacial CEC process. Furthermore, experiments conducted under simulated environmental contact conditions substantiated that CEC to contributes to ROS generation in natural scenarios. In summary, this work provided the first systematic elucidation of ROS generation via CEC at iron mineral-water interfaces, implying the catalytic potential of common iron minerals in soil under natural mechanical action. It provides a new pathway and perspective for abiotic ROS formation in the soil environments and offers a novel theoretical framework that advances the fundamental understanding of soil environmental ROS sources.

# Emerging Contaminants in Soil, Water, and Plant Systems: One Health Perspective

**Wei Zhang**[1*]

[1]*Department of Plant, Soil and Microbial Sciences, Michigan State University, East Lansing, MI, United States*

*weizhang@msu.edu

**ABSTRACT**

Mitigation of emerging contaminants in soil, water, and plant systems is critical to protecting agriculture, ecosystems, and human health. One Health approach is needed to address the new threats posed by environmental emerging contaminants through interdisciplinary research. This presentation highlights our recent studies: 1) antibiotics, bacterial communities, and antibiotic resistance genes in vegetables upon antibiotic exposure; 2) sorption and internalization of silver nanoparticles by plants and effectiveness of vegetable washing procedures; 3) study and management of the entire metal(loid)s (metallome) in carrot and wheat as influenced by soil water conditions, plant growth stages, and soil amendment application; 4) training machine learning models to predict the uptake and accumulation of per- and polyfluoroalkyl substances (PFAS) by crops; 5) simulating interactions of prion fibrils between metal ions or model geosorbent surfaces using molecular dynamics. These studies can improve our fundamental understanding on environmental processes and impacts of emerging contaminants and further help us develop scientifically-sound mitigation and management strategies.

# Microbial potential to mitigate neurotoxic methylmercury accumulation in farmlands and rice

**Kang-Hua Chen[1], Yu-Rong Liu[2*], and Hanzhong Jia[1*]**

[1] *College of Natural Resources and Environment, Northwest A&F University, Yangling, China*

[2] *College of Resources and Environment, Huazhong Agricultural University, Wuhan, China*

**ABSTRACT**

Toxic methylmercury ($CH_3Hg^+$) is produced by microbial conversion of inorganic mercury in hypoxic environments such as rice paddy soils, and can accumulate in rice grains. Although microbial demethylation has been recognized as a crucial pathway for $CH_3Hg^+$ degradation, the identities of microbes and pathways accountable for $CH_3Hg^+$ degradation in soil remain elusive. Here, we combine $^{13}CH_3Hg^+$-DNA stable-isotope probing experiments with shotgun metagenomics to explore microbial taxa and associated biochemical processes involved in $CH_3Hg^+$ degradation in paddy and upland soils. We identify *Pseudarthrobacter*, *Methylophilaceae* (MM2), and *Dechloromonas* as the most significant genera potentially engaged in the degradation of $^{13}CH_3Hg^+$ in paddy soil with high mercury contamination. We confirm that strains affiliated with two of those genera (species *Dechloromonas denitrificans* and *Methylovorus menthalis*) can degrade $CH_3Hg^+$ in pure culture assays. Metagenomic analysis further reveals that most of these candidate $^{13}CH_3Hg^+$ degraders carry genes associated with the Wood-Ljungdahl pathway, dicarboxylate-hydroxybutyrate cycle, methanogenesis, and denitrification, but apparently lack the *merB* and *merA* genes involved in $CH_3Hg^+$ reductive demethylation. Finally, we estimate that microbial degradation of soil $CH_3Hg^+$ contributes to 0.08-0.64 fold decreases in $CH_3Hg^+$ accumulation in rice grains across China (hazard quotient decrements of 0.62%-13.75%). Thus, our results provide insights into microorganisms and pathways responsible for $CH_3Hg^+$ degradation in soil, with potential implications for development of bioremediation strategies.

# Comparison for colloidal stability and aggregation behavior of fulvic and humic acids: effects of cations and pH

**ABSTRACT**

Fulvic acid (FA) and humic acid (HA) are organic materials that can form complexes with metal ions, playing a crucial role in predicting the behavior of organic colloids. The colloidal stability values of FA and HA vary with pH and specific cations, but this has rarely been comprehensively examined. This study systematically compared the aggregation kinetics and colloidal stability of FA and HA and the mechanisms behind their behavior based on particle interaction theory. The results showed that higher pH values stabilized FA and HA colloids by increased electrostatic repulsive energy. Additionally, increased electrolyte concentration destabilized FA and HA colloids by cationic polarization (chemical bond formation). The cation aggregation ability followed the order $Ca^{2+}$ > $Mg^{2+}$ > $K^{+}$ > $Na^{+}$, showing that the specific ion effects induced by nonclassical polarization resulted from the strong electric field of the highly negatively charged FA and HA. With pH values ranging from 5 to 7 and 9, FA and HA were stabilized through raising the critical coagulation concentrations (CCCs) in NaCl and KCl. With increasing pH, the enhanced electrostatic repulsive energies in the Na+ and K+ systems resulted in weaker aggregation behaviors due to the deprotonation of the hydroxyl and carboxyl groups of colloids. Compared with HA, FA had a lower Hamaker constant, higher surface negative charges, larger CCCs, and stronger dispersion stability. This work will contribute to the understanding of organic colloidal aggregation mechanisms and act as a References to predict their environmental behaviors.

# The fate of endocrine disruptor compounds in soil. The role of humic substances

**N. Senesi[1*] and E. Loffredo[1]**

[1] *Dept of Soil, Plant and Food Sciences, University of Bari "Aldo Moro", Bari, Italy*

*nicola.senesi@uniba.it

**ABSTRACT**

Endocrine disruptor compounds (EDCs) are hormone-like substances that include natural and synthetic estrogens and several pesticides, industrial chemicals, and plastic and pharmaceutical products and byproducts, which are able to alter, i.e., disrupt, the normal endocrine functions in humans and animals. These compounds may enter the soil through current agricultural practices and/or disposal of urban and industrial effluents, sludges and wastes. The estrogenic risk of EDCs is generally related to their distribution and speciation in the various soil phases, in which adsorption/desorption processes play a very important role. Humic substances, particularly their humic acid (HA) fractions, are universally acknowledged to be among the most chemically and biologically reactive components of soil. In this work, adsorption kinetics and adsorption/desorption isotherms of the EDCs bisphenol A (BPA), octyl-phenol (OP), 17-alpha-ethynyl estradiol (17ED) onto HA samples isolated from the surface (0-30 cm) and subsurface (30-90 cm) horizons of two sandy soils were determined using a batch equilibrium method and high performance liquid chromatography (HPLC).

The adsorption kinetics of EDCs by HAs was clearly distinguished in two phases, a rapid one in the first few hours (h) of contact, which corresponded to more than 90% of the total amount adsorbed, and a slow one that needed generally less than 24 h to be completed. Experimental adsorption data were best fitted in a Langmuir-type isotherm for BPA and 17ED, in a linear isotherm for OP, and in a non-linear, L-shaped Freundlich isotherm for EED. These results indicated that no limiting adsorption/saturation occurred for EED and OP onto the HAs examined over the concentration range tested, whereas a maximum adsorption, i.e., saturation, was reached by BPA and 17ED. In general, the HAs isolated from surface soils exhibited a much larger adsorption capacity for any EDC examined than that of HAs isolated from subsurface soil. The extent of adsorption of BPA was generally smaller than that of the other three EDCs, which were adsorbed at almost the same extent. The adsorption of EED, and especially of BPA, onto HAs was generally reversible, with desorption occurring quickly and almost completely after few desorption steps. On the contrary, adsorption of OP was almost irreversible, with partial desorption occurring slowly, and high amounts of OP retained by most HAs at the end of the experiment. The desorption was not studied for 17ED.

In conclusion, the soil HAs examined in this work were able to adsorb variable amounts of the four EDCs studied that would tend to accumulate in the soil surface horizon. However, BPA and EED could be quickly and completely desorbed, so these EDCs can be expected to move downward in the soil profile, which implies a serious risk of contamination of groundwater. Differently, OP was slowly and only partially desorbed, thus it can be expected to remain mostly adsorbed by HAs, especially on the surface soil layer, leading to the risk of a corresponding, more or less permanent top soil contamination.

**ABSTRACT**

In the context of globally increasing nitrogen (N) deposition, understanding how N inputs affect carbon (C) cycling in vulnerable ecosystems through plant–microbe interactions is essential for accurately predicting the carbon budget of terrestrial ecosystems. Dryland ecosystems, such as desert steppes, are particularly sensitive to exogenous N inputs due to their inherently low nutrient availability and fragile ecological structure. However, the mechanisms through which N deposition modulates belowground C processes—especially via changes in root exudation and associated microbial activity—remain inadequately understood. This study focuses on a desert steppe ecosystem, with the overarching aim of deciphering the "plant–microbe interaction" pathway through which N deposition influences soil organic carbon (SOC) transformation. Specifically, we investigate how N-induced shifts in the chemical composition of root exudates drive functional changes in rhizosphere microbial communities and subsequently alter the dynamics of SOC components. Methodologically, we employ an integrated multi-omics and soil biogeochemical approach. Root exudates are characterized using untargeted metabolomics to reveal their chemical diversity and compositional changes under N enrichment. These metabolic profiles are then correlated with key plant functional traits and soil abiotic factors (e.g., pH, available N, moisture). In the rhizosphere soil, we measure the activities of key hydrolytic and oxidative enzymes involved in C and N cycling. High-throughput sequencing of bacterial and fungal communities, coupled with functional gene quantification, is used to assess shifts in microbial taxonomic composition and functional potential. Furthermore, soil C fractions—including particulate organic C (POC) and mineral-associated organic C (MAOC)—are quantified to evaluate changes in SOC stability and turnover. By synthesizing data from root exudate metabolomics, microbial community and functional analyses, and soil C fractionation, this research aims to systematically unravel the cascading mechanism of "root exudates → microbial community structure/function → SOC transformation" in desert steppes subjected to N deposition. The study is expected to provide novel insights into the biochemical and microbial linkages that mediate ecosystem C responses to N enrichment.

# Effects of Microplastic Pollution on Soil Organic Carbon Turnover

Yanpei Li[1], Hanzhong Jia[2]*

State Key Laboratory of Soil and Water Conservation and Desertification control, College of Natural Resources and Environment, Northwest A & F University, Yangling 712100, China

**ABSTRACT**

Microplastics (MPs, <5 mm) are recognized as an emerging contaminant in terrestrial ecosystems. MPs can directly influence soil organic carbon (SOC) turnover by serving as a carbon source and altering soil physicochemical properties. They also indirectly modify carbon cycling by influencing nutrient supply, microbial communities and functions, faunal ecological roles, and plant growth. Here, we investigated the relationships between MPs pollution and SOC turnover. A two-year-long field experiment showed opposite effects of conventional microplastics and biodegradable microplastics on plant residue decomposition. Conventional microplastics inhibited microbial biomass carbon and enzyme activities and reduced decomposition, while biodegradable microplastics increased soil nutrient levels, supported soil microbes and improved microbial diversity, and promoted decomposition. Another six-month soil microcosm experiment confirmed that MPs, particularly the non-biodegradable type, shifted soil aggregates from macro- to microaggregates, reduced aggregate stability, increased light fraction organic carbon, and promoted SOC transformation. In addition, $CO_2$ emissions were higher in MPs treatments than in controls, and $\delta^{13}C$ isotope tracing showed that priming effects were increased with both aggregate size and MPs concentration. Overall, MPs reshape SOC turnover through combined effects on soil aggregates and soil microorganisms, and conventional and biodegradable MPs show contrasting impacts.

# Sulfur Dynamics Coupled with Heavy Metal Behavior under Fluctuating Redox Conditions in Paddy Soils

**Nanaho Shimono[1], Toru Hamamoto[1], and Tomoyuki Makino[1*]**

[1] *Graduate School of Agricultural Science, Tohoku University, Miyagi, Japan*

*tomoyuki.makino.d6@tohoku.ac.jp

**ABSTRACT**

Intermittent irrigation, commonly known as alternate wetting and drying (AWD), is widely promoted in paddy fields to mitigate methane emissions. AWD induces fluctuations between reducing and oxidizing states in soils, which can reorganize the coupled cycling of sulfur (S) and heavy metals (HMs). While recent studies have shown that microbial activity in reduced paddy soils promotes the formation of $Cu_2S$ via biologically mediated sulfide production (Xu et al., 2023), the oxidation pathways of $Cu_2S$ following the disturbance of reducing conditions remain unresolved, particularly during brief oxygen exposure. This study aimed to elucidate the early-stage oxidation pathway of $Cu_2S$ in reduced paddy soils and to determine whether this process proceeds beyond sulfide minerals toward sulfate formation.

Three Japanese paddy soils (Brown Lowland soils, Gray Lowland soils, and Gley soils) were incubated under flooded conditions to establish reducing environments. After reduction was confirmed by redox potential (Eh) measurements, brief oxygen bubbling was applied to induce a transient oxidation event, followed by re-establishment of flooded conditions. During incubation, plant-available S and 0.1 M HCl-extractable HMs as a labile pool of HMs in the soils were quantified. Additionally, solid-phase Cu speciation was identified using Cu K-edge X-ray absorption near-edge structure (XANES) analysis.

Under reducing conditions, plant-available S and 0.1 M HCl-extractable Cu decreased markedly, indicating Cu immobilization as sulfide minerals. Subsequent short-term oxygen bubbling caused a clear increase in 0.1 M HCl-extractable Cu, whereas plant-available S showed no recovery, indicating negligible sulfate production. This asymmetric response suggests that $Cu_2S$ was not oxidized to sulfate but was partially transformed into CuS during the short-term oxidation. Cu K-edge XANES analysis confirmed the formation of CuS following transient oxidation, demonstrating that oxidation proceeded only to an intermediate sulfide phase.

Given the extremely short duration of the oxidation treatment, the observed $Cu_2S$-to-CuS transformation is best explained by initial abiotic oxidation rather than microbially mediated processes. Importantly, this reaction pathway—partial oxidation of $Cu_2S$ to CuS without re-oxidation of sulfide to sulfate—has not been previously reported in paddy soils. These findings reveal a previously unrecognized early-stage oxidation mechanism of copper sulfides under fluctuating redox conditions and provide new insight into Cu stability and transformation in reduced soil environments.

## ABSTRACT

Desertification is one of the most critical environmental degradation processes in semi-arid regions, leading to vegetation loss, enhanced erosion, and profound changes in surface soil geochemistry. In this context, soil biological crusts (SBCs) play a crucial role in protecting the soil surface and regulating the availability of metals and nutrients, particularly in degraded areas with sparse vegetation cover. This study aimed to evaluate the influence of SBCs on the accumulation and distribution of iron (Fe), manganese (Mn), zinc (Zn), copper (Cu), and phosphorus (P) in areas exhibiting different degradation levels within the Médio Jaguaribe Desertification Nucleus, Ceará State, Brazil.

A total of 70 paired samples of surface soil (0–10 cm) and SBCs were collected across three representative areas: degraded, recovering, and References (non-degraded). Concentrations of Fe, Mn, Zn, and Cu were determined by atomic absorption spectrometry, phosphorus by molecular spectrophotometry, and pH by potentiometric methods. Differences in metal and phosphorus concentrations between soils and SBCs within each area were assessed using Student's *t*-test or the non-parametric Mann–Whitney test, according to data distribution.

Higher accumulation of Mn and P in SBCs compared to adjacent soils was observed in all areas, with statistically significant differences consistently associated with higher concentrations in the crusts. These results highlight SBCs as effective surface compartments for retaining these elements. In the degraded area, SBCs exhibited substantially higher concentrations of Zn and Cu than the underlying soil, indicating that under conditions of severe degradation and low plant cover, SBCs play a central role in metal immobilization. This retention, mediated by Fe and Mn oxides and organic substances present in SBCs, contributes to reducing phosphorus losses via erosion and leaching, thereby enhancing nutrient cycling in degraded, phosphorus-poor environments.

In landscapes with low plant density, SBCs fill critical ecological gaps at the soil surface, assuming essential geochemical regulatory functions. Overall, SBCs demonstrate a high capacity to immobilize metals and phosphorus in disturbed environments, particularly in degraded areas, confirming their direct influence on surface soil geochemical dynamics in desertification-prone regions.

# Surface-Modified Carbonaceous Media for Enhanced Removal of Short-Chain Per- and Polyfluoroalkyl Substances from Urban Stormwater

**Nourin I. Seenthia[1], Yunqiao Guan[1],Yeo-Myoung Cho[2], Lee Blaney[3], Wenqing Xu[1]***

**ABSTRACT**

Per- and polyfluoroalkyl substances (PFAS) in urban stormwater represent a persistent environmental and public health concern, particularly for short- and ultrashort-chain compounds that are not effectively removed by conventional treatment technologies. This study evaluates the performance of surface-modified carbonaceous sorbents designed to improve the removal of short-chain PFAS in stormwater biofiltration systems. Two classes of modified carbonaceous materials were investigated: carbon materials functionalized with nitrogen-containing surface groups and biochar modified through the incorporation of metals.

Eight short- and ultrashort-chain PFAS were selected as target compounds, including perfluorobutanoic acid (PFBA), perfluorobutanesulfonic acid (PFBS), perfluoropentanoic acid (PFPeA), perfluoropentanesulfonic acid (PFPeS), perfluoropropanoic acid (PFPrA), perfluoropropanesulfonic acid (PFPrS), trifluoroacetic acid (TFA), and trifluoromethanesulfonic acid (TFMS). These compounds span carbon chain lengths from one to four carbons and include both carboxylate- and sulfonate-terminated functional groups. Nitrogen functionalization was achieved through covalent grafting of cationic nitrogen-containing moieties (i.e., quaternary ammonium and pyridine) onto carbon surfaces, while metal incorporation into biochar was used to introduce additional electrostatic attraction. Sorbent performance was assessed using batch adsorption experiments and continuous-flow column studies representative of engineered stormwater media filters. A one-dimensional intraparticle pore diffusion model was applied to both modified and unmodified carbonaceous materials, with model parameters estimated from experimental breakthrough data and used to predict full-scale filter performance under idealized operating conditions.

Results showed that PFAS chemical structure, including carbon chain length and terminal functional group, strongly influenced removal behavior across all materials. Nitrogen-functionalized activated carbon exhibited enhanced adsorption kinetics and higher adsorption capacity relative to unmodified materials, particularly for sulfonate-containing PFAS, consistent with improved external mass transfer and accelerated pore diffusion. Metal-incorporated biochar provided additional PFAS retention benefits. Sorption data were best fitted by the Freundlich isotherms for most target compounds. Column experiments demonstrated that modified carbonaceous materials substantially delayed PFAS breakthrough compared to unmodified media, and model simulations predicted multi-fold increases in filter lifetime. Collectively, these results indicate that surface modification of carbonaceous media through nitrogen functionalization and metal incorporation is an effective strategy for improving short- and ultra-short chain PFAS removal and extending the operational lifespan of stormwater treatment filters.

**ABSTRACT**

Changing redox conditions in paddy system, influenced by water, fertilizer, and photothermal processes, lead to high reactive oxygen species (ROS) production, which affects soil pollutant transformation. Studying ROS at the soil-redox interface is challenging due to their reactivity, diversity, and short lifespan.

In this study, we conducted rice potting experiments to quantitatively identify and spatially portray the dynamic processes involved in ROS formation across multiple interfaces—namely the overlying water, soil-water interface, and soil layer—within paddy systems during diurnal cycles. We employed techniques such as real-time molecular probe capture, in situ imaging using fluorescent films, and machine-learning modeling.

Our findings revealed that the generation of ROS within the paddy system's overlying water and at the soil-water interface reached its zenith during 13:00-15:00, delineating a daily pattern marked by pronounced peaks at noon and comparatively diminished levels in the morning and evening hours. The spatial distribution pattern for ROS production was identified as follows: soil-water interface > soil layer > overlying water; under different weather scenarios: sunny day > rainy day > cloudy day. Importantly, exogenous oxidative deposition substances such as hydrogen peroxide ($H_2O_2$) and rainfall inputs into the paddy system were found to significantly enhance ROS production ($p < 0.05$). Furthermore, illumination, temperature, Eh, and exogenous $H_2O_2$ inputs exhibited highly significant positive correlations ($p < 0.05$) with ROS levels within the paddy system; notably, illumination emerged as a key abiotic factor influencing ROS formation. Additionally, soil ROS act as a microbial metronome, transducing weather cues to orchestrate microbial community assembly.

The results of this research elucidate the mechanisms underlying ROS formation at multiple interfaces in paddy system throughout diurnal cycles while providing a theoretical foundation for a deeper understanding of environmental impacts associated with ROS dynamics in these agricultural systems.

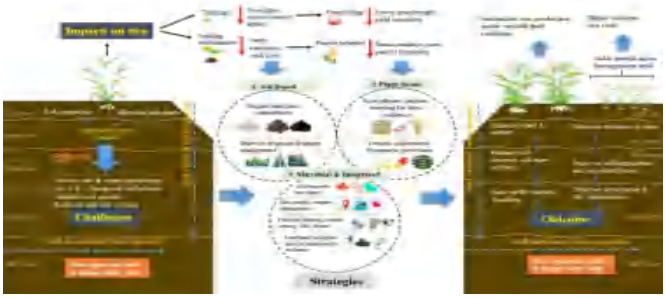
**ABSTRACT**



Soil salinity, sodicity, and alkalinity are frequently intensified by field-scale heterogeneity characterized by uneven spatial distribution of salts, moisture, and nutrients. In rice systems under sodic, saline-sodic soil conditions, such heterogeneity leads to uneven crop stands, variable plant responses, and challenges in applying uniform management practices. Worse, such fields receive different amounts of amendments, while similar field management practices are frequently supplemented, reducing the efficiency of amelioration. Meanwhile, field operations such as land leveling and ploughing further redistribute salts, probably creating new heterogeneity patterns. Currently, traditional methods fail to address these complexities, resulting in inconsistent growth, inefficient resource use, and variable yields. Despite these challenges, no systematic review has addressed them. This review fills the gap by examining how spatial variability in physico-chemical and biological factors affects rice performance at critical growth stages. It also evaluates integrated strategies, including organic/inorganic amendments, irrigation and drainage, and rice varieties and their cultivation to improve rice productivity under these conditions. Our review suggests focusing on the interaction between soil heterogeneity and plant growth, and on integrating plant- and soil-based management strategies with site-specific technologies, with particular focus on the critical growth stages of rice, where targeted interventions can significantly and effectively enhance rice performance in heterogeneous sodic/saline-sodic soils.

**ABSTRACT**

Phenanthrene (PHE), a representative polycyclic aromatic hydrocarbon, readily bioaccumulates in soil organisms and poses substantial ecological risks. However, accurately predicting PHE toxicity across heterogeneous soils remains challenging due to complex soil-organism interactions. In this study, a machine learning (ML) framework was developed to predict PHE toxicity. Laboratory toxicity assays in 24 typical Chinese soils revealed a strong linear relationship between internal concentration ($C_e$) of PHE and earthworm fecundity, described by linear regression (LR). A comprehensive database encompassing soil physicochemical properties and PHE concentration ($C_s$) was constructed to support $C_e$ prediction. Among 11 ML algorithms evaluated, CatBoost exhibited superior performance ($R^2$=0.8), identifying $C_s$ as the primary determinant of $C_e$, followed by key soil properties (pH, soil organic matter). The integrated CatBoost-LR model accurately predicted toxicity ($R^2$=0.81) within external verification and enabled spatial assessment of PHE-associated ecological risks across China. These findings demonstrated that ML can quantitatively link soil properties to pollutant bioaccumulation and toxicity, providing a powerful, data-driven tool for ecological risk assessment of organic contaminants in complex terrestrial environments.

**ABSTRACT**

This study presents the results of research on the content of different potassium forms and the relationships between them in soil samples collected from 13 soil profiles located in Mongolia. According to the WRB soil classification system, the analyzed soils were classified into seven soil groups: Calcisols, Solonetz, Cambisols, Umbrisols, Kastanozems, Chernozems, and Phaeozems. The following forms of potassium were determined in the soil samples: water-soluble potassium, active potassium extracted with 0.01 mol·dm$^{-3}$ $CaCl_2$, plant-available potassium determined using the CAL method, exchangeable potassium extracted with 1 mol·dm$^{-3}$ $NH_4HCOO$, weakly fixed potassium extracted with 2 mol·dm$^{-3}$ HCl, strongly fixed potassium extracted with 1 mol·dm$^{-3}$ $HNO_3$ under hot conditions, reserve potassium extracted with 20% HCl under hot conditions and total potassium determined by digestion in a mixture of HF and $HClO_4$. The analyzed soil samples from profiles located in the desert and steppe zones of Mongolia were characterized by high contents of all analyzed potassium forms. The surface horizons of the analyzed soils were classified as having medium to very high potassium status. The highest accumulation of all studied potassium forms was observed in the surface horizons of the analyzed soil profiles. The content of the analyzed potassium forms followed the following increasing sequence: K-$H_2O$ < K-$CaCl_2$ < K-CAL < K-2M HCl < K-1M $HNO_3$ < K-20% HCl < K-HF.

The fixed potassium content in the analyzed soil samples was high and, on average, was three times higher than the exchangeable potassium content.

*E-mail Address of Presenting Author: wangyuncheng@issas.ac.cn

## ABSTRACT

Fast and real-time detection of trace Hg(II) by fluorescent probes under acidic conditions is urgently required due to the high toxicity and accessibility to creatures and human being. However, fluorescent probes for Hg(II) detection in environmental samples are rarely reported due to the protonation potential of acidic mercury sources. In this study, the SD probe was developed by 5-(p-dimethylaminobenzylidene) rhodanine (DMABR) loaded on sepiolite by hydrothermal treatment, and showed excellent Hg(II) detection performances for mercury sources at pH 4–10 due to buffering ability of the hyperconjugated lactam rings. Sepiolite functioned as the support skeleton to decrease intermolecular transition, and thus increased the sensitivity. At pH 4, the SD probe showed high selectivity and sensitivity for Hg(II) among various species, with low LOD and binding constant of $4.78 \times 10^{-9}$ M and $1.34 \times 106$ $M^{-1}$, respectively. Through DFT calculations, MAS $^{1}$H NMR and 2D-COS analysis, the detection mechanism was demonstrated as $SN_1$ substitution of the spontaneous leaving H on amino groups in the transient state during tautomeric equilibrium, rather than the expected high-affinity sulphydryl. Additionally, the SD probe exhibited promising potential in quantifying water-soluble and bioavailable Hg(II) in acidic polluted soil and water samples. Moreover, real-time detection was realized by paper-based strips.

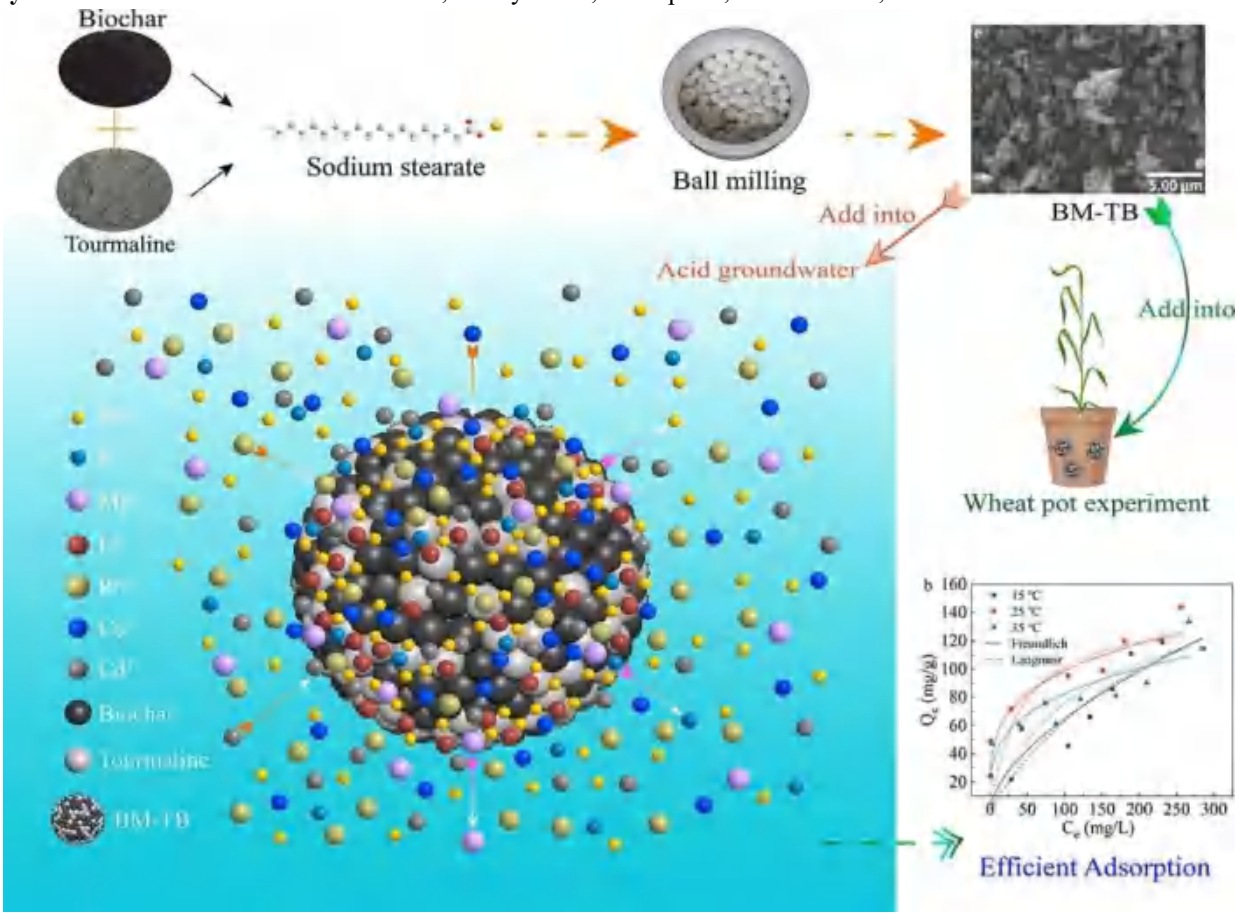
# Novel Ball-Milled Tourmaline-Biochar Composite: Application in Heavy Metal-Contaminated Groundwater and Bottom Sediment Remediation



**Weicheng Wang[1], Qing Zhu[1], and Cuipin Wang[1*]**

*[1] Key Laboratory of Pollution Processes and Environmental Criteria, Ministry of Education, Tianjin Key Laboratory of Environmental Remediation and Pollution Control, College of Environmental Science and Engineering, Nankai University, Tianjin 300071, China*

**ABSTRACT**

A novel composited material of ball-milled tourmaline-biochar (BM-TB) developed have a good adsorption capacity for heavy metal in the wider pH ranges of the aqueous solution. The adsorption capacity of BM-TB for $Cd^{2+}$ was 142.6 mg/g when the solution pH was 4.0, and when pH was higher than 4.0. When the BM-TB was used to adsorb As, Cd, Cu and Pb from the groundwater, the adsorption percentage obtained 17.4 %, 93.6 %, 64.1 % and 95.9 %, respectively. When the BM-TB was used to remediate the soil, BM-TB can the can significantly reduce the bioavailability of Cu, Cd, Pb, Zn and As and inhibit their enrichment into plant. Additionally, the novel material was remediated the soil, it can amend the bottom mud and enhance the content of dissolved inorganic carbon (DIC), total nitrogen and rapidly available potassium, and significantly reduce the content of dissolved carbon (DC), dissolved organic carbon (DOC) and total dissolved nitrogen (TDN). In addition, the increase of $CO_2$ emission flux was not significant, and gradually decreased with the increase of culture days. The present study provided not only a novel material, but also technology protocol for treatment of acidic wastewater and heavy metals contaminated groundwater and soil.

**ABSTRACT**

The distribution and speciation of soil phosphorus (P) in the solid phase are critical for understanding its biogeochemical transformations and bioavailability to plants. This study investigated P fractions in soils from extensively grazed desert and steppe grasslands in Mongolia, encompassing seven soil types: Calcisols, Cambisols, Solonetz, Phaeozems, Umbrisols, Kastanozems, and Chernozems.

Soil P was fractionated using the sequential Hedley procedure, which separates operationally defined pools including: readily soluble P (extracted with water, $P_{H2O}$), exchangeable/labile P ($P_{EX}$), P bound to Fe and Al oxides ($P_{Fe/Al}$), P associated with Ca ($P_{Ca}$), and residual P (Pres). Plant-available P was additionally assessed using the calcium-acetate-lactate (CAL) extraction method.

Total soil P concentrations varied widely across the studied soils, ranging from 330.4 to 2957.8 mg P $kg^{-1}$. The distribution of P fractions was strongly influenced by soil type and horizon.

Labile and readily available P forms ($P_{H2O}$ + $P_{EX}$, corresponding to the most plant-accessible pools) constituted only a minor proportion of total P, accounting for 0.60% to 7.47%. In contrast, the majority of P was present in recalcitrant forms, predominantly Ca-bound P ($P_{Ca}$) and residual P (Pres), which together comprised 84–99% of total P.

These results indicate that, despite high total P contents in many of the analyzed soils, the proportion of readily plant-available P was generally low. This suggests limited immediate bioavailability of soil P in these arid and semi-arid Mongolian grassland ecosystems, likely due to strong fixation in stable Ca-associated and residual pools, with implications for plant nutrition and ecosystem productivity under extensive grazing management.

**ABSTRACT**

In the context of global climate change in recent decades, extensive data on carbon (C) stocks and dynamics in terrestrial landscapes and in the ocean have been obtained. We know much less about the C cycle in the contact zone of the sea and land – in coastal landscapes. This is due to the complexity of coastal landscapes, where the C source is not only biogenic accumulation, but also the contribution of terrigenous runoff, as well as the input and removal due to the activities of the sea. “Blue carbon” includes the organic carbon (OC) stocks stored by the ocean and the coastal ecosystems (mangroves and marshes) responsible for the long-term OC storage. The main scientific objective of our research was to assess the reserves and dynamics of OC in the biomass and soil organic matter of wetlands on the shores of the seas of the western part of the Arctic Ocean and to model their dynamics under a changing climate.

In soils of marsh ecosystems of the Pomorsky coast of the White Sea C on the most moribund part of the coastal zone was accumulated due to the input of allochthonous, thalassogenic organic matter: the maximum stocks at the lower marsh level are 31.6 $t \cdot ha^{-1}$. At a distance from the boundary of daily flooding, soil C stocks were higher due to biogenic accumulation of organic matter: the maximum value at the upper marsh level is 77.1 $t \cdot ha^{-1}$. Soils of marsh ecosystems of the Pomorsky coast of the White Sea are characterized by low values of $CO_2$ emission (98±16 $mgCO_2 \cdot m^{-2} \cdot h^{-1}$), which indicates their low biological activity. $CO_2$ emission from soils of marsh ecosystems of the southeastern coast of the Barents Sea were high (4.03±0.17 $g\ CO_2 \cdot m^{-2} \cdot day^{-1}$), which indicated their high biological activity. Soils at different levels of marsh ecosystems statistically significantly differ in the value of $CO_2$ emission and are arranged in a series by increasing its values: watts, beaches < littoral baths, eroded marsh ledges < ecotone zones, lower marshes, splash zones of return flow channels (creeks) < middle and upper marshes. The dynamics of the Barents Sea shores were assessed using satellite data. On average for all profiles over the entire study period (1961-2015), the shore dynamics is low (the average rate for all profiles was –0.01 $m \cdot year^{-1}$), but in some periods, significant reformation of different direction was observed along the entire shore.

Climate change, manifested in rising sea levels, increased storm activity and coastal erosion, leads to increased C fluxes from the pedosphere into the hydrosphere and atmosphere. The results of the study contribute to a better understanding of the role in the C balance of coastal ecosystems of the western sector of the Russian Arctic and similar landscapes.

**ABSTRACT**

Mineral-catalyzed Maillard reactions have been proposed as a plausible abiotic pathway for the formation of organic carbon in soil. However, the molecular characteristics of the resulting Maillard products and their linking to real soil organic matter (SOM) remain poorly understood. Here, we conducted abiotic incubation experiments using glucose and glycine as model soil precursors with ferrihydrite (Fh) and birnessite (δ-MnO2) catalysis under environmentally relevant conditions. FT-ICR-MS analysis revealed that both minerals significantly accelerated the polymerization, yielding products that were predominantly categorized as recalcitrant lignin-like compounds, including C15H18O5N2, C16H23O6N3, C18H26O5N2, C19H28O6N2, and C23H33O4N3. Molecular reaction network analysis showed that glucose addition reaction (+ C6H10O5), glycine addition reaction (+ C2H3NO), Strecker degradation (− CO2), and retro-aldol reactions (− C3H6O3 or − C4H8O4) played key roles in molecular evolution. The catalytic mechanisms of Fh and δ-MnO2 were found to be consistent, involving electron acceptance from reducing sugars and cation bridging via dissolved metal ions. Notably, 52.2–84.8% Maillard-like molecules in real soil dissolved organic matter samples, suggesting that the Fh- and δ-MnO2-catalyzed Maillard reactions may represent a significant while previously underappreciated contributor to SOM formation. Together, these findings offer new insights into the mineralogy-mediated pathways that govern the molecular polymerization and persistence of organic carbon in soil systems.

## ABSTRACT

Land use change is a global driver of carbon (C) cycle. The conversion of natural ecosystems to cropland decreases soil C stocks due to removal of plant biomass and increase in soil organic matter (SOM) mineralization because of reduction in C protection caused by tillage. Degraded cropland soils are restored after their abandonment from agricultural use and partially recover organic C stocks. Accumulated organic C serves as a structural and energetic source for soil microorganisms. We used a chronosequence of abandoned croplands (forest steppe zone, MAP: 270-450 mm, MAT: -0.7 °C, soil: loamy Haplic Luvisol) to examine effects of natural restoration on SOM stability and energy storage in soil. We used thermal approach (thermogravimetry and differential scanning calorimetry) combined with 180-day soils incubation and SOM density fractionation.

The soils sequestered 0.85 Mg C $ha^{-1}$ $y^{-1}$ (0-30 cm) during 25 years after cropland abandonment. In abandoned soils, thermally labile SOM with an activation energy of 69 kJ·$mol^{-1}$ accumulated 2.8 times faster than did stable SOM with a higher energy barrier to combustion (80 kJ·$mol^{-1}$). Microorganisms use mainly thermally labile SOM, whose content decreased by 10–24% over 180 days of soil incubation. The increase in energy availability and microbial activity in restored soils led to faster C and nutrient cycling in the abandoned cropland than in current agricultural lands. Mineral-associated organic matter stored 1.7 times more energy per unit of C (42 kJ·$g^{-1}$C) than did the free and occluded particulate organic matter (25 kJ·$g^{-1}$C). Free particulate organic matter was the dominant energy pool in the restored soil and increased microbial activity. Restored and natural soils had a lower thermal stability of SOM and greater microbial decomposability than the cropland soils.

Due to the preferential accumulation of C with lower thermal stability and with greater susceptibility to microbial decomposition in the restored soils, greater $CO_2$ release could occur if these lands are retiled – will be involved again in agricultural use. The content of thermally stable C also increased in abandoned soils; therefore, we should account for the ecological balance between C sequestration and release after the natural restoration of croplands.

[2] *Institute of Soil Science, Chinese Academy of Sciences, 211135 Nanjing, China*

**ABSTRACT**

Dissolved organic matter (DOM), being the most reactive soil organic matter (SOM) fraction, affects key biogeochemical processes in soil like nutrient cycling, pollutant transport, and organic carbon sequestration. Quantitative understanding of physical-chemical processes regulating the release of DOM in response to variation in factors such as pH and Ca concentration is still lacking. Here, we conducted batch experiments and employed the NOM-CD (Natural Organic Matter-Charge Distribution) model and the NICA-Donnan (Non-Ideal Consistent Competitive Adsorption-Donnan) model to investigate the physical-chemical processes controlling DOM release in seven agricultural topsoils under varying pH (3-9) and Ca concentration (0-10 mM). The DOM fractionation results showed that while hydrophilic acid (Hy), fulvic acid (FA), and humic acid (HA) concentrations increased with pH, their contribution to total DOM differed: Hy and HA dominated at respectively low pH (~4-6) and high pH (~8-9), whereas FA peaked at near-neutral pH (~6.5-7). Our NOM-CD model calculations revealed that changes in the DOM concentration at low pH (pH<~5-6.5) were mainly due to OM desorption from soil minerals. Changes in the DOM concentration at high pH (pH>~5-6.5) were predominantly controlled by OM dissolution, as demonstrated by the relation between the DOM concentration and Donnan potential ($\varphi_D$) of DOM calculated with the NICA-Donnan model. Based on these findings, we propose a conceptual Dual-Domain Desorption Dissolution model in which the relative importance of these two controlling mechanisms is quantitatively assessed for the first time. These insights will be helpful to better quantify soil management effects on the stability and functioning of SOM.

# Abiotic Methane Production Driven by Soil Reactive Oxygen Species

**ABSTRACT**

Methane ($CH_4$) emissions from wetlands are traditionally attributed to microbial methanogenesis under anoxic conditions. However, recent studies have suggested that non-enzymatic, reactive oxygen species (ROS)-driven processes may also produce $CH_4$ in biological systems. Here, we extend this concept to soil environments and demonstrate that ROS can drive substantial abiotic $CH_4$ formation during redox fluctuations in wetland soils. Through controlled incubations of soils collected from 14 wetlands across China, we show that fluctuating redox conditions promote ROS generation, which in turn oxidizes soil organic matter and yields $CH_4$ abiotically.

These findings reveal that abiotic $CH_4$ formation is not a rare or laboratory-specific phenomenon but a widespread and dynamic process within natural wetland ecosystems. By coupling the redox cycling of iron, organic matter, and ROS, this mechanism operates independently of microbial methanogenesis yet contributes measurably to total $CH_4$ fluxes. Our results challenge the long-held assumption that wetland $CH_4$ emissions are solely biological in origin and call for a reassessment of methane budgets that overlook abiotic sources. Furthermore, we show that hydrological management strategies including alternate wetting and drying (AWD), commonly implemented to mitigate $CH_4$ emissions, may unintentionally enhance ROS-driven abiotic $CH_4$ production. Recognizing and quantifying this process provides a new framework for understanding methane cycling under fluctuating redox conditions and offers critical insights for greenhouse gas mitigation in wetland and agricultural systems.

**ABSTRACT**

The Altai and Tianshan Mountains of eastern Kazakhstan represent two major ecological and climatic barriers in Central Asia and are warming substantially faster (0.27–0.45 °C decade$^{-1}$) than most temperate regions (0.15–0.25 °C decade$^{-1}$; IPCC, 2023). Such accelerated warming and increasing drought are expected to alter soil organic matter (SOM) dynamics, yet the controlling factors of SOM stability in this mountain ecosystems remain poorly resolved. In this study, 48 soil samples were collected in the Altai and Tianshan Mountains, ranging from around 500 m to 3000 m in elevation. Rock-Eval® thermal analysis was used to quantify long-term SOM stability ($PARTY_{SOC}$ stable OC content) and chemical stability (R-index). Pyrolysis-GC/MS was used to investigate SOM molecular composition of the soils. Links among SOM molecular composition, climatic parameters and other soil properties were investigated using principal component analysis, multiple regression analysis, and correlation analysis. We found that climatic and mineralogical factors jointly structured SOM molecular composition, which was highly sensitive to vegetation, exchangeable Ca/Mg, Al/Fe oxides, elevation, MAT and aridity. The first composition axis (PC1) contrasted plant-derived structural biopolymers with condensed aromatic–N-rich material: scores were high in samples enriched in lignin-derived compounds, long-chain lipids and terpenoids, and low where bulk aromatics and N-heterocyclic compounds dominated. The second axis (PC2) primarily captured a gradient from carbohydrate- and short-chain lipid-rich SOM (high scores) towards N-containing and aromatic-enriched fractions (low scores). Chemical stability ($R^2$ = 0.84) was overwhelmingly governed by molecular composition, with a strong negative effect of PC1 (Std.Est = −0.85), and was further modulated by aridity. This indicates that chemically resistant SOM fractions in this region are tightly coupled with both molecular architecture and drought stress. In contrast, long-term SOM stability was governed predominantly by exchangeable Ca/Mg and Al/Fe oxides, with only secondary contributions from SOM composition, indicating stabilization via associations of SOM with exchangeable Ca/Mg and Al/Fe oxides. These results suggest that ongoing climate change is likely to have a strong impact on the chemically resistant SOM pool, whereas the long-term stable SOM pool may be comparatively buffered on decadal timescales under climate change.

**ABSTRACT**

Addressing the challenge of improving soil health and carbon sequestration through sustainable agricultural practices requires a deeper understanding of how management strategies shape soil biota and organic matter (OM) dynamics across the entire soil profile. Soil biota is a key driver of nutrient cycling and carbon stabilization, yet processes occurring in the subsoil remain poorly understood. Our study aimed to investigate how different farming systems affect the structure of bacterial, fungal and invertebrate communities from 0–60 cm depth, and how any shifts relate to OM distribution, quality and stocks.

A 10-year wheat-maize rotation trial on a Calcaric Eutric Cambisol in central Italy was assessed, by comparing: i) integrated management without cover crops and conventional tillage (CONV); ii) organic management with grass-legume cover crops, temporary wheat-faba bean intercropping and conventional tillage (ORG); and iii) integrated management with grass-legume cover crops and no-tillage (NOT). Soils were sampled by genetic horizons. Microbial and metazoan communities were assessed via DNA metabarcoding (16S, ITS, COI), and OM was fractionated into labile, stable and resistant pools. Bulk soil and fractions were analyzed for organic carbon and total nitrogen, and their stocks were estimated. Further, available phosphorous was measured in bulk soil, and the chemical composition of mineral-associated OM (MAOM) was studied by $^{13}C$ NMR.

Significantly ($p < 0.05$) higher bacterial and fungal richness was observed in NOT topsoil and subsoil, respectively. diversity clearly separated NOT from ORG and CONV, also indicating enhanced depth-dependent differentiation under no-tillage. ORG and CONV showed no significant differences in and diversity, although the relative abundances of few taxa differed, e.g. ORG was enriched in rhizobia (genera *Mesorhizobium* and *Bradyrhizobium*), even at greater depths than NOT.

OM patterns reflected similar biota differences. NOT promoted OM stratification due to no-tillage, with higher content in topsoil and greater abundance of labile forms, also in MAOM. ORG and CONV had more homogenized OM distribution along the soil depth, dominated by stable and more decomposed pool. However, ORG and NOT recorded higher proportion of sand-size aggregates and associated OM, suggesting improved structural development driven by cover crops. Total OC stocks (0–60 cm) did not differ significantly among systems.

In conclusion, reduced disturbance and continuous organic inputs reshape soil biota and OM dynamics across depth, altering community structure and carbon stabilization pathways.

**ABSTRACT**

Thomas (1996) claimed that "Soil pH is probably the single most informative measurement that can be made to determine soil characteristics". Soil pH buffering capacity (pHBC) determines the resilience of soils to acidification, yet its national-scale distribution across China's croplands remains poorly quantified. In this study, 22 representative soil samples covering major agroecological zones were analyzed to develop pHBC prediction models based on key physicochemical properties, including carbonate content, cation exchange capacity (CEC), and particle-size distribution. Multiple linear regression (MLR), ridge regression (RR), and least absolute shrinkage and selection operator (LASSO) models were compared, with MLR demonstrating superior predictive performance and interpretability ($R^2$=0.95 for alkaline–neutral soils and 0.77 for acidic soils). Using the optimal MLR models and national soil datasets, the first spatially explicit map of cropland pHBC across China was generated using 1083 national soil physicochemical grid data published by (FAO&IIASA, 2023), revealing a pronounced north–south gradients (**Fig.1**, <8 to >800 mmol $kg^{-1}$ $pH^{-1}$). High pHBC zones occur primarily in calcareous soils of northern and northwestern China, whereas low pHBC values dominate in the highly weathered acidic soils of the south. Building upon this, a novel index, soil acidity debt, was proposed to quantify the total proton load a soil can absorb before reaching the critical pH threshold of 5.5. The resulting map shows that 49.3% of China's cropland remains acid-safe, 35.3% is at potential risk, and 15.4% has exceeded its buffering limit. Spatial divergence in acidity debt reflects the combined effects of carbonate buffering, climatic leaching, and anthropogenic nitrogen inputs. The integrated pHBC–acidity debt framework provides a quantitative foundation for precision liming, sustainable fertilizer management, and region-specific soil remediation, offering new insight into soil acidification dynamics and a scientific basis for national soil conservation policy.

**ABSTRACT**

Understanding controls on soil organic carbon (SOC) stabilization is essential for predicting its distribution and sequestration potential. Controls on mineral-associated organic carbon (MAOC), the dominant long-term SOC pool, remain poorly understood across pH gradients, particularly in tropical and subtropical regions. Here, we analyzed topsoils from 66 non-volcanic sites under mainly natural vegetation in India, Tanzania, Cameroon, Japan, and Indonesia, spanning broad gradients in SOC (1.2–50.7 g $kg^{-1}$), moisture (EP, effective precipitation, −1740 to 2850 mm), and corresponding pH (3.9–9.2). Soils were grouped as strongly acidic (pH ≤ 5.5), weakly acidic (5.5 < pH ≤ 7), and alkaline (pH > 7). We quantified MAOC (> 1.7 g $cm^{-3}$ and < 53 µm), microbial necromass, and key predictors including active Al/Fe (oxalate-extractable Al + Fe), clay content, and exchangeable Ca + Mg. Structural equation models (SEMs) quantified the contributions of MAOC-related factors. C-stabilization capacity of active Al/Fe (mol C per mol active Al/Fe) was derived from unstandardized SEM coefficients.

MAOC comprised 77 ± 15% of SOC across sites, with acidic soils showing higher SOC, MAOC, and active Al/Fe. Correlation and SEMs identified active Al/Fe, rather than clay content, as the primary positive regulator of MAOC. pH-stratified SEMs showed active Al/Fe content explained most of the variation in MAOC across all pH classes ($\beta > 0.47$, $R^2 > 0.78$ in all, strongly acidic, and weakly acidic soils; $\beta = 0.59$, $R^2 = 0.53$ in alkaline soils). Exchangeable Ca + Mg did not significantly influence MAOC, even in alkaline soils, indicating that Ca and Mg play a minor role in MAOC stabilization at this scale. The C-stabilization capacity of active Al/Fe was similar in strongly and weakly acidic soils (5.6 mol C per mol active Al/Fe) but lower in alkaline soils (3.7 mol C per mol active Al/Fe), likely due to reduced positive surface charge and fewer reactive hydroxyls. Necromass C was substantially higher in acidic than alkaline soils, and its proportion in MAOC (64 ± 22%) and positive correlation with active Al/Fe occurred only in acidic soils. This indicates that MAOC formation in acidic soils is closely tied to Al/Fe-mediated stabilization of microbial necromass via charge-driven sorption and ligand exchange. The non-necromass component of MAOC also increased with active Al/Fe but showed little pH dependence, suggesting robust inner-sphere complexation or Al/Fe-mediated aggregation. Together, active Al/Fe controls MAOC across tropical and subtropical soils, but its C-stabilization efficiency is pH dependent because microbial necromass is preferentially stabilized in acidic soils, leading to a lower MAOC in alkaline soils. Thus, both active Al/Fe abundance and pH (influenced by effective precipitation) must be considered when predicting MAOC stocks, composition, and SOC sequestration potential.

**ABSTRACT**

Carbon sequestration by application of organic materials and biochar in soil is an important strategy to increase soil organic carbon (SOC), but the stability of SOC, particularly humic substances (HS) vary with the types of organic material. In this study, cotton straw and its derived compost and biochar were added with equivalent carbon content to soil and incubated for 180 days. The structural characteristics of humic acid (HA), fulvic acid (FA) and humin (Hu) were investigated using solid-state $^{13}C$ nuclear magnetic resonance (NMR) and Fourier transform infrared (FTIR) spectroscopy. The results showed that biochar treatment increased the aryl C of HA, FA, and Hu by 1.38%, 1.68%, and 10.46% compared to straw treatment and increased the aryl C of HA, FA, and Hu by 1.46%, 1.99% and 2.01% compared to compost treatment. The O-alkyl C of HA was 10.59% and 10.65% in high biochar/straw and biochar/compost ratios respectively, while it was 9.81% and 9.61% in low biochar/straw and biochar/compost ratios. In addition, the O-alkyl C of FA was 62.83% and 58.48% in high ratios of biochar/straw and biochar/compost, respectively, while it was 55.85% and 55.94% in low ratios of biochar/straw and biochar/compost. These results suggest that biochar is advantageous for aryl C formation of FA and Hu due to its high aryl C content, whereas straw or compost is advantageous for alkyl C formation of HA. The stability of aryl C and O-alkyl C of HA, FA, and Hu can be improved in soils by incorporating biochar in combination with straw or compost.

**ABSTRACT**

Microbial respiration is the conventional paradigm for explaining short-term pulsed releases of $CO_2$ during soil drying–rewetting (D/RW) cycles. However, a rapid pulse onset and lagging microbial recovery have been measured in soils that experienced severe drought after D/RW, raising the question of whether abiotic carbon mineralization is also a prevalent phenomenon, particularly in sandy soils with prolonged aridity. Through soil incubation experiments, including microbial growth monitoring and sterilization, we identified the crucial role of abiotic processes in soil organic carbon (SOC) mineralization during D/RW. In sandy soil, abiotic processes accounted for 95.5% of total $CO_2$ emissions within three hours of rewetting, compared to only 39.5% in paddy soil. Concurrently, the solid-liquid reaction in D/RW process mediated the redox cycle of Fe, Mn, and reactive oxygen species (ROS) production, directly promoting SOC mineralization. Further, ROS participated in SOC degradation through synergistic effects with enzyme activity. These abiotic processes mainly resulted in removing molecules with low H/C ratios (<1.24) and high unsaturation in DOM, which are more difficult for microbes to degrade. Our findings highlight the importance of abiotic reactions in short-term SOC mineralization after D/RW process, offering a novel framework for evaluating carbon emissions in sandy soils of arid and semi-arid regions.

# Carbon sequestration dynamics of MAOC in the tea plantation with different ages: evidence from Fe/Al oxides and organo–mineral interactions

**Tiantian Tang[1*], Tao Liu[1], and Tingxuan Li[1]**

*[1] Key Laboratory of Investigation and Monitoring, Protection and Utilization for Cultivated Land Resources, Ministry of Natural Resources, College of Resources, Sichuan Agricultural University, Chengdu 611130, China*

**ABSTRACT**

Mineral-associated organic carbon (MAOC) is critical for long-term soil carbon sequestration, yet its accumulation dynamics and constraints in acidic agroecosystems remain unclear. Using a chronosequence (6, 20, 29 years) of tea plantations, we investigated the dynamics of MAOC and its mineralogical characteristics in topsoil (0-20 cm) and subsoil (20-40 cm). We found that while MAOC stocks increased with plantation age, its accumulation rate significantly declined, especially in subsoils. Sequential extraction revealed that organically complexed Fe/Al ($Fe/Al_{PP}$) was the dominant form of mineral-associated carbon. However, the formation of $Fe/Al_{PP}$ was suppressed over time, directly limiting further MAOC increase. Mineralogical and spectroscopic analyses showed that prolonged tea cultivation promoted the transformation of reactive, high-surface-area Fe phases (e.g., ferrihydrite) to more crystalline, low-surface-area goethite, reducing the reactive mineral surface area available for carbon binding. Concurrently, the chemical nature of MAOC shifted from plant-derived alkyl-C to microbial-derived, oxygen-rich carboxylic/amide-C. These bulky, hydrophilic molecules create a "crowding effect," sterically hindering the formation of stable inner-sphere complexes on remaining mineral surfaces. We conclude that the deceleration of MAOC accumulation in acidic tea soils is co-limited by the depletion of reactive Fe/Al phases and the progressive occupation of mineral surfaces by less-stabilizable, microbial-processed organic matter. This dual mechanistic constraint defines the finite saturation capacity of MAOC in these important carbon-sink ecosystems.

# Establishing trees into permanently grazed grassland to increase SOC stocks – scaling results from microbes to landscapes

**Sam McNally[1*], Scott Graham[1], Kara Allen[1], Ziva Louisson[1], Manpreet Dhami[1], Pierre Roudier[1], Dan Richards[1], David Whitehead[1]**

*[1]Bioeconomy Science Institute (Manaaki Whenua Group, Lincoln, New Zealand)*

*mcnallys@landcareresearch.co.nz

**ABSTRACT**

New Zealand has moderate to high levels of soil organic carbon (SOC) in part due to the temperate climate, soil mineralogy and dominance of permanently grazed grassland land use. To offset greenhouse gas emissions and meet New Zealand's net zero target, a focus has been on establishing new extensive permanent forests to act as a carbon sink. We hypothesised that a targeted integration of smaller groupings of trees within grassland soils could achieve significantly greater carbon stocks, per unit land area due to the presence of edge effects, whereby increases in SOC stocks could also occur.

Here we will present findings and insights from a large national scale research programme investigating whether the integration of small grouping of trees within grazed grasslands can increase SOC stocks. We quantified and examined the relationship between SOC stock, soil fractions (POC and MAOC) and microbial abundance along grassland to forest gradients.

Our evidence suggests that integration of trees into grassland soils can increase SOC stocks in certain soil types, particularly those with a lower capacity to store carbon (e.g. soils with a low surface area). We also measured a change in microbial composition along these grassland to forest gradients with metagenomics data underway to understand whether this change in composition caused a change in microbial function.

Furthermore, data from this research programme is being used to validate and parameterize a microbially-informed model to allow predictions of changes in soil carbon stocks associated with the establishment of trees within grassland soils. The outcome of these model scenarios will be incorporated into geospatial models to project SOC scenarios at the landscape to national scale.

# Non-linear regulation of soil organic carbon by salinization: aggregate–microbe coupling

**Yuanduo. Wang, Mengyuan. He, Junhua. Zhang***

*School of Life Sciences, Ningxia University, Yinchuan 750021, China*

**ABSTRACT**

Soil salinization and alkalization are key environmental factors limiting agricultural productivity and soil carbon sequestration. Labile and recalcitrant carbon pools play distinct roles in maintaining carbon balance, yet their responses to different types and degrees of salinization remain unclear. Here, we investigated three typical saline–alkaline soils (saline, sodic, and secondary salinized) in the Ningxia Irrigation District, analyzing soil physicochemical properties, aggregate structure, carbon fractions, enzyme activity, and microbial communities across four salinization levels (non-, light, moderate, and high). Results showed that across the salinization gradient, macroaggregates became fragmented, microaggregates were enriched, and soil structural stability declined significantly (decreased MWD and GMD, increased D and PAD), thereby weakening the physical protection of organic carbon. Labile carbon pools (POC, DOC, MBC) exhibited a >60% reduction , whereas recalcitrant carbon (MAOC) remained relatively stable. Enzyme activities and microbial diversity declined significantly, with community composition shifting toward halotolerant and oligotrophic taxa. Region-specific patterns were observed: the three soil types (saline, sodic, and secondary salinized) exhibited labile carbon loss and relative preservation of recalcitrant carbon, but the dominant mechanisms differed. In saline (HN) and sodic (XDT) soils, carbon dynamics were primarily governed by salinity stress and aggregate degradation, while in secondary salinized soils (HSB), the coupling of aggregates and microbial function enhanced the transformation of carbon into mineral-associated forms, supporting a relatively stable recalcitrant carbon pool. This study reveals the multi-pathway regulation of soil organic carbon under salinization, highlighting the non-linear response of carbon stability to soil type and formation process, and provides theoretical guidance for ecological restoration and carbon sequestration management in saline–alkaline soils.

**Keywords:** Saline–alkaline soils, Soil aggregates, Microbial community, Labile carbon, Recalcitrant carbon, Carbon stability

# Interactive effects of straw and biochar reorganize humic acid molecular architecture toward coupled reactivity and persistence

## ABSTRACT

Humic acid (HA), a key component of soil humic substances, plays a crucial role in soil fertility and ecological functioning. To elucidate the structural heterogeneity of HA under the interactive effects of straw and biochar, we conducted a systematic incubation experiment with single and combined applications of straw and biochar. Multiple complementary techniques (including elemental analysis, electron paramagnetic resonance (EPR), fluorescence spectroscopy, solid-state $^{13}C$ nuclear magnetic resonance (NMR), and Fourier transform ion cyclotron resonance mass spectrometry (FTICR-MS)) were employed to characterize HA at the molecular level. Organic amendments significantly increased the oxygen content, polarity, and hydrophilicity of HA molecules, while also enhancing free-radical concentrations and molecular-level structural complexity. Biochar addition primarily promoted aromaticity and supramolecular condensation, whereas straw inputs enriched oxygenated moieties and increased molecular biodegradability. Strikingly, their combined application enhanced radical concentration and chemical activity while generating less condensed aromatic structures, resulting in HA molecular assemblages that combine features commonly associated with higher chemical reactivity and increased structural persistence.

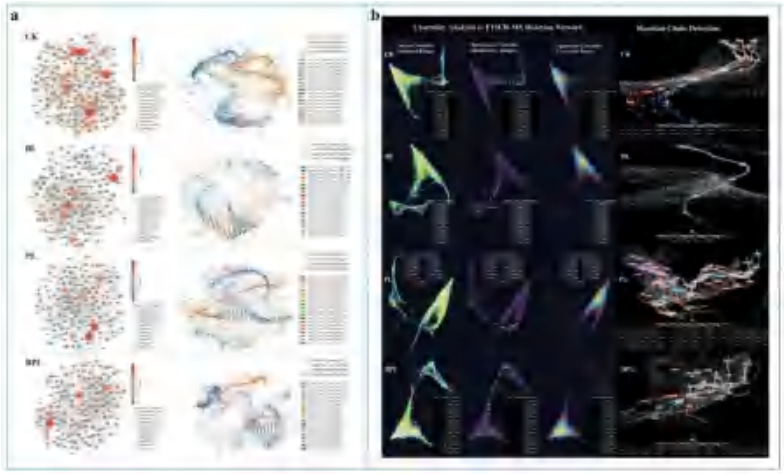

Figure 1. Network organization and modular structure of humic acid (HA) molecular assemblages under different treatments (a), and centrality landscape(left) and reaction backbone chain detection(right) of HA molecular reaction networks under different treatments (b).

Together, these results support a conceptual framework linking reactivity and stability, in which labile and recalcitrant organic inputs are associated with distinct yet integrated patterns of HA molecular organization. Beyond site-specific implications, this study provides new strategies and theoretical foundations for optimizing soil organic matter stability and fertility, offering guidance for sustainable agricultural management and carbon sequestration.

**ABSTRACT**

In high-latitude arable systems (63.9°N), short growing seasons and cold climates often constrain regenerative practices. This study investigates how cover crop (CC) diversity influences the synergy among root development, carbon (C) persistence, and nutrient (N and P) dynamics within a Nordic barley (*Hordeum vulgare L.*)-oat (*Avena sativa*) rotation. Over three years, we evaluated a gradient of CC intercropping complexity using a randomized complete block design. Treatments were: (1) Control (barley without NPK), (2) Biochar-Fertilizer (barley + NPK + 1.8 Mg $ha^{-1}$ $year^{-1}$ biochar), (3) Monocrop (barley), (4) Ryegrass (barley + ryegrass), (5) Clover (barley + ryegrass + white/red clover), and (6) Chicory (barley + ryegrass + red clover + chicory + bird's-foot trefoil). We quantified root biomass, soil organic matter (SOM) fractions , specifically Mineral-Associated Organic Matter (MAOM) and Particulate Organic Matter (POM), aggregate stability, nutrient stocks, and microbial abundance via qPCR.

The CCs were successfully established, with an average biomass of 1525 kg/ha, without compromising cereal yields, thereby confirming their viability in Nordic climates. A central finding was that root development served as the primary driver of organo-mineral associations. Ryegrass- and Clover-based systems produced significantly higher root biomass, which correlated strongly ($p < 0.01$) with MAOM stocks and total P acquisition. These systems stored 12 Mg/ha more MAOM-C and 1.1 Mg/ha more MAOM-N than the control at 0-20 cm depth.

The inclusion of diverse functional traits in the complex five-species mixture significantly improved soil physical structure, yielding higher aggregate stability and lower bulk density. While CCs accumulated approximately 7 kg P/ha, the diverse mix optimized nutrient availability, whereas simpler mixtures showed higher C:P ratios, suggesting potential microbial P immobilization. Microbial abundance was consistently higher in multi-species treatments, indicating a more active biological environment.

Ongoing analysis integrates cereal physiological data, focusing on the photosynthetic efficiency of oats in response to these altered nutrient regimes. These findings bridge the gap between root architecture, plant physiology, and long-term SOM persistence, providing a strategic framework for using functional crop traits to enhance soil resilience and nutrient efficiency in cold-climate regions.

# Molecular–thermal coupling of plant residue-derived organic matter mediated by clay minerals: insights from solid-state 13C NMR

**Xiaodong Chen[1*], Noriko Yamaguchi[2], Ryoko Senda[3], Yuki Mori[1] and Syuntaro Hiradate[1]**

**ABSTRACT**

Clay minerals strongly influence the persistence of soil organic matter (SOM), yet the links between mineral-specific molecular transformations and organic matter (OM) stability remain insufficiently quantified. We incubated *Artemisia princeps* residues for 360 days in quartz-, kaolinite-, and montmorillonite-based artificial soils and characterized plant-derived OM associated with these minerals using solid-state $^{13}C$ CP/MAS NMR and thermogravimetry–differential thermal analysis (TG–DTA). In quartz soil, $^{13}C$ NMR spectra showed a shift from O-alkyl-dominated, polysaccharide-rich material to residues enriched in alkyl- and carbonyl-C, with smaller changes in aromatic-C, providing an unprotected decomposition baseline. Kaolinite-associated OM retained relatively high O-alkyl-C and showed only moderate increases in alkyl- and carbonyl-C, resulting in low alkyl/O-alkyl ratios and more plant-like signatures, indicating that kaolinite slows both decomposition and structural transformation. By comparison, montmorillonite-associated OM had the lowest O-alkyl-C, the highest alkyl- and carbonyl-C, slightly elevated aromatic-C, and alkyl/O-alkyl > 1, indicating selective accumulation of highly processed, alkyl- and carboxyl-rich residues on 2: 1 clay. These mineral-specific NMR patterns suggest distinct clay controls: kaolinite dampens the progression from plant-like to microbially transformed OM, whereas montmorillonite sustains a sorption-constrained, low-flux OM – microbe – clay microenvironment in which strong mineral protection suppresses net $CO_2$ production and microbial metabolism, yet gradual compositional shifts can accumulate during slow turnover of mineral-associated OM. TG–DTA further showed higher decomposition temperatures and larger residual mass for clay-associated OM than for quartz. By integrating NMR and thermal data into simple indices of estimated mean residence time (*eMRT*) and activation-energy equivalent (*Ea-equivalent*), we quantified how these energetic parameters covary with alkyl/O-alkyl ratio and related molecular features. Overall, different clay minerals impose contrasting C-stabilization regimes that co-shape OM molecular composition and energetic resistance, highlighting mineral-specific molecular–thermal coupling as a key control on the stabilization of plant residue-derived SOM in clay-rich soils.

**ABSTRACT**

Retaining soil organic carbon (SOC) and understanding its stability/persistence are essential for achieving long-term carbon sequestration goals, maintaining soil fertility, and promoting soil health. Soils vary in their potential for carbon sequestration. Understanding the biophysical limits of different soils helps identify regional, soil-specific management strategies and determine the maximum storage capacity of SOC, especially in organo-mineral associations constrained by reactive minerals. These processes range from global factors, such as climate, to complex soil biogeochemical interactions at organo-mineral surfaces. Therefore, improving our understanding of the dynamics that contribute to SOC persistence—from the microscale to the soil profile and landscape level—as well as the mechanisms that protect it, enhances our ability to predict changes in the soil carbon reservoir amid global environmental shifts. Organo-mineral interactions have been regarded as the primary mechanism for stabilizing SOC over decades to millennia. Although substantial progress has been made in understanding carbon persistence and turnover, the fundamental mechanisms that underlie pedogenic soil properties remain underinvestigated. This research analyzes SOC to evaluate stability, persistence, and carbon sequestration potential, based on soil properties at the molecular and microstructural levels, in Solonetzic and Vertisolic soils from southern Saskatchewan in the Canadian portion of the North American Prairie. In the Fall of 2025, three intact soil core samples—3 inches in diameter and 24 inches deep from the surface—were collected from both Vertisolic and Solonetzic soils, classified in the field under the Canadian Soil Classification System. Three replicates per location were obtained using a punch truck. The study employs synchrotron-based X-ray Computed Tomography (CT) to obtain three-dimensional microstructural data, enabling visualization and analysis of pore size, connectivity, distribution, and volume, as well as the spatial arrangement of SOC fractions relative to soil features and pore spaces. X-ray fluorescence imaging (XRF) will map carbon content and composition, providing a detailed view of the distribution of total SOC and identifying carbon-rich zones. Near-edge X-ray absorption fine structure (NEXAFS) spectromicroscopy will produce spatially resolved data on SOC species by analyzing intact samples containing root fragments, SOC, and soil pores. Fitting the obtained data to References spectra will identify spatial patterns of aromatic, aliphatic, and carboxylic carbon compounds associated with different features. This research provides critical visual insights into how pore structures affect the distribution of organic molecules; hence, understanding the molecular details of SOC in specific pedogenic soil types can inform soil management practices aimed at carbon sequestration by leveraging the soil's inherent capacity.

**ABSTRACT**

The interaction between soil organic carbon (SOC) dynamics and microbial activity is crucial for understanding the mechanisms that govern carbon storage and turnover in terrestrial ecosystems. Changes in precipitation patterns can significantly affect SOC distribution and cycling processes by altering vegetation structure, which, in turn, influences regional ecosystem carbon balances. However, the systematic understanding of SOC turnover, particularly in deep soil layers, and its microbial driven mechanisms across varying precipitation gradients during afforestation remains limited. To address this, our study examines afforestation chronosequences across three distinct precipitation gradients: semi-arid, arid, and hyper-arid regions. At each gradient, soil samples were collected from depths of 0-500 cm from plots representing five vegetation restoration years, with non-afforested land employed as the control. Using a combination of physical SOC fractionation and radiocarbon dating techniques, we characterized the dynamics and turnover times of deep SOC and its fractions over the vegetation restoration process. Furthermore, molecular ecological approaches were used to analyze shifts in microbial community composition, abundance, and functional groups involved in carbon cycling, with particular emphasis on identifying key carbon-sequestering microbial phylum, carbon cycling genes and their associations with specific SOC fractions. This research aims to elucidate the microbial mechanisms responsible for the accumulation and stabilization of deep SOC during vegetation restoration. By integrating data across precipitation gradients, vegetation restoration years, microbial communities, and SOC turnover, we aim to clarify the interactions among these factors. Our findings are expected to advance the understanding of climate and ecosystem carbon cycle feedbacks and offer empirical guidance for enhancing vegetation restoration and carbon management strategies in dryland regions.

## ABSTRACT

Vegetation restoration is a critical strategy for rehabilitating ecosystems in alpine arid regions, influencing the vertical distribution of soil organic carbon by regulating microbial community structure. However, the microbial mechanisms underlying this process remain poorly understood. Therefore, this study investigates the microbial effects of vegetation restoration on soil organic carbon within the 0–500 cm soil profile, comparing planted *Caragana microphylla* shrub forest and mobile dunes (CK) at different restoration ages (5, 10, 15, 23, and 36 years) in the Gonghe Basin, China. The study area is situated at an elevation of 2,871 to 3,870 meters above sea level, with an annual mean temperature of 3.9°C and average annual precipitation of 246.3 mm, primarily occurring between May and September. The annual mean potential evaporation is 1,716.7 mm, resulting in an exceptionally arid climate. This region is classified as an alpine arid zone, with predominantly sandy soils. Results indicate that the mean soil organic carbon content within the 0–500 cm soil profile was 1.18 $g \cdot kg^{-1}$, with reserves ranging from 55.82 to 144.99 $t \cdot hm^{-2}$. Microbial biomass carbon averaged 4.11 $mg \cdot kg^{-1}$. With increasing vegetation restoration duration, soil organic carbon content and reserves in the 0–500 cm profile exhibited distinct trends at 5, 10, and 15 years, showing significant increases at 23 and 36 years of restoration. At 23 years, soil organic carbon content and reserves in the 0–500 cm profile were 1.5 and 1.8 times those of the control (CK), respectively, while at 36 years, these values were 1.8 and 2.2 times those of CK. Vertically, soil organic carbon content initially decreased, followed by an increase across all restoration periods. Moisture emerged as a key environmental factor regulating deep soil organic carbon sequestration in alpine arid regions. Microbial biomass carbon exhibited a significant positive correlation with soil organic carbon content. Microbial α-diversity within the 0–500 cm soil profile increased markedly with restoration duration, while microbial gene abundance associated with carbon sequestration functions significantly increased during the later restoration phases. In summary, vegetation restoration drives changes in microbial community structure and carbon sequestration capacity by altering soil structure, thereby promoting deep soil organic carbon accumulation. This study elucidates the microbial mechanisms underlying soil carbon sink formation during vegetation restoration in alpine arid regions from the perspectives of microbial diversity and carbon sequestration genes, offering significant implications for ecological restoration and carbon management in degraded alpine desert areas.

## ABSTRACT

Mineral-associated organic carbon (MAOC) constitutes a crucial and stable fraction of soil organic carbon (SOC), yet its formation is regulated by minerals with distinct properties and varying capacities to bind organic carbon (OC). Although the influence of mineral type on MAOC is recognized, the underlying mechanisms remain inadequately understood. In this study, pot experiments were used to assess the influence of three soil minerals (montmorillonite, ferrihydrite, and kaolinite) on the quantity and composition of SOC fractions and the structure of bacterial communities. Mineral additions increased MAOC contents by 14% to 42%, accelerated O-alkyl C degradation, and enhanced recalcitrant alkyl C and aromatic C sequestration. The mineral treatments preserved OC by enhancing Fe minerals rather than expanding the surface area of MAOC. Synchrotron radiation–based Fourier transform infrared spectroscopy revealed that montmorillonite and ferrihydrite strengthened the interactions between clay minerals, Fe oxides, and microbial-derived peptides, whereas kaolinite weakened those associations. Furthermore, nano-scale secondary ion mass spectrometry provided direct evidence that montmorillonite and ferrihydrite enhanced spatial coupling between soil C and minerals, in contrast to kaolinite. Additionally, all three treatments significantly increased bacterial community diversity and altered community composition, primarily shifting the relative abundances of dominant phyla *Firmicutes*, *Proteobacteria*, and *Bacteroidota*. These findings elucidate mineral-specific pathways through which soil minerals regulate OC stability and offer a scientific basis for designing management strategies to enhance SOC sequestration.

## ABSTRACT

Despite widespread land degradation land-use change across African ecosystems, depth-resolved evidence monitoring ecosystems that stabilize soil organic carbon (SOC), sustain crop productivity and remain chemically safe remains limited. This study quantifies SOC stabilization mechanisms, nutrient dynamics, heavy metal safety and crop productivity across model ecosystems in Africa. We applied stratified soil sampling across depths (≤150 cm), physical SOC fractionation, greenhouse gas flux measurements, heavy metal analyses, crop yield assessments and long-term chronosequence comparisons across multiple sites and land-use systems. Cocoa agroforestry showed an initial 18 % SOC decline after forest conversion, followed by recovery to 121 Mg C $ha^{-1}$ after 45 years, with cocoa aged ≥18 years exceeding forest SOC at 20–60 cm depth, while maintaining bulk densities below critical thresholds. Forest islands stored up to 200 Mg C $ha^{-1}$ and 15 Mg N $ha^{-1}$ at 0–30 cm depth, with trees enhancing particulate organic matter and aggregate-protected carbon near canopies. Findings in soil organic carbon pools including dissolved organic carbon, particulate organic matter, silt + clay, sand + stable aggregates and recalcitrant SOC fractions ($R_{SOC}$) in the forest islands, natural savannas and smallholder farms across West Africa generally reflected the complex interplay among vegetation shifts, climatic controls, soil properties and human factors on carbon and nitrogen dynamics. Croplands in African dark earths (AfDEs) in Ghana at the 0–10 cm depth stored higher SOC stocks (20–50 Mg C $ha^{-1}$) than non-AfDE croplands (8–27 Mg C $ha^{-1}$), with 53–89 % of carbon stabilized in mineral-associated pools and cumulative $CO_2$ emissions representing <2 % of stored carbon. Except for Hg, Mn, Zn, Cd, As, Pb and Ni remained below USEPA thresholds. The AfDEs produced higher maize yields without fertilizer inputs (≈2.60 t $ha^{-1}$ grain; ≈4.07 t $ha^{-1}$ stover). Near these scalable ecosystems, the CarbonXtras Project is current deploying near-real-time carbon monitoring sensors in Ghana to support low-emission practices through regenerative practices and market premiums. Together, these ecosystems will underpin regenerative and climate-smart land restoration in Africa.

# Arbuscular Mycorrhizal Fungi Strengthen Aggregate Protection and Reactive Fe/Al Pools to Stabilize Soil Organic Carbon in Acidic Soils

**Wenqi Zhang[1*], Xin Guan[1], and Jiang Jiang[1]**

[1] *College of Forestry and Grassland,College of Soil and Water Conservation,*

*Nanjing Forestry University, Nanjing 210037, China*

*zhangwenqi@njfu.edu.cn

**ABSTRACT**

Acidic-soil organic carbon (SOC) stability is controlled by two key pathways: (1) physical occlusion within soil aggregates and (2) mineral protection through SOC binding to Fe/Al (hydr)oxides. Arbuscular mycorrhizal fungi (AMF) may reshape both pathways via hyphal networks and the production of binding organic substances. However, their net effect and dominant mechanisms in acidic environments remain unclear. Here we used an acidic soil and established a controlled experiment that separated root and hyphal pathways. We quantified aggregate size distribution and SOC partitioning among aggregate fractions, and we assessed the physical protection of SOC by aggregates using incubation-based mineralization. In parallel, we measured mineral-associated organic carbon and multiple operationally defined Fe and Al pools to track coupled changes in structural and mineral protection.

Our results show that AMF reduced the proportion of microaggregates and increased the formation of large aggregates, indicating improved aggregate stabilization. In line with these structural changes, reactive pools of Fe and Al increased under AMF. Specifically, oxalate-extractable aluminum (Al_o) and oxalate-extractable iron (Fe_o) increased, and the ratios Al_o/Al_d (Alo relative to dithionite-extractable aluminum, Al_d) and Fe_o/Fe_d (Fe_o relative to dithionite-extractable iron, Fe_d) also increased. These patterns suggest a greater contribution of short-range-order Fe/Al phases and/or stronger organo-mineral associations.

Incubation results further indicate stronger physical protection of SOC in AMF treatments. When aggregates remained intact, SOC mineralization rates and cumulative $CO_2$ emissions were lower than in the non-AMF treatment. After aggregate disruption, differences among treatments became much smaller. This pattern indicates that AMF enhances aggregate formation and occlusion, reduces carbon accessibility, and suppresses mineralization. Overall, AMF caused coordinated shifts toward stronger aggregate occlusion and larger reactive Fe/Al pools. These results support a coupled mechanism in acidic soils, where structural and mineral protection jointly enhance SOC stabilization, and provide a testable framework for mycorrhiza-mediated SOC persistence.

## ABSTRACT

Black carbon (BC) is widely recognized for its potential to enhance soil carbon (C) sequestration, yet its influence on soil C dynamics remains complex and context-dependent. In this study, we demonstrate that BC can paradoxically accelerate $CO_2$ emissions in upland soils through coupled iron (Fe) redox cycling. Under aerobic conditions, BC promotes abiotic oxidation of Fe(II) to Fe(III), enhancing the decomposition of native soil organic C. Conversely, under anaerobic conditions, BC functions as an electron shuttle, stimulating microbial Fe(III) reduction and further accelerating C mineralization. To investigate the role of mineralogical context, soils were amended with either ferrihydrite or goethite, with or without BC. Comparative analysis revealed that the type of Fe mineral critically modulates the magnitude of BC-induced C loss, with ferrihydrite exhibiting a stronger response due to its higher reactivity.Mechanistic investigations integrated multiple scales of evidence. Soil chemistry analysis showed dynamic changes in Fe speciation, while enzyme assays revealed enhanced activities of C- and Fe-related enzymes. Measurements of soil electron transfer capacity and free radical generation indicated that BC facilitates both abiotic redox reactions and microbial respiration. Microbial community profiling and gene expression analysis further confirmed that BC enriches Fe-reducing bacteria and upregulates key genes involved in anaerobic iron reduction, establishing a direct link between microbial metabolism and enhanced C turnover. Collectively, these results demonstrate that BC accelerates soil C mineralization through a combination of abiotic Fe oxidation, microbial Fe reduction, and enhanced electron transfer processes. This study challenges the conventional view of BC as a persistent carbon sink in soils, highlighting its potential to increase C emissions under specific mineralogical and redox conditions. Our findings underscore the critical importance of considering Fe mineral type and redox status when evaluating BC amendments for soil C management. By providing a multi-scale mechanistic understanding of BC-induced soil C dynamics, this work informs both fundamental research on soil biogeochemistry and practical strategies for carbon sequestration and climate mitigation.

# Effects of Human Land Use Practices on the Binding Patterns of Organic Carbon and Iron Oxides

**Ping Lu[1*], Zhong-Xiu Sun[1] and Si-Yi Duan[1]**

*[1] College of land and environment, Shenyang Agricultural University Shenyang, Liaoning CHINA*

*2362745980@qq.com

**ABSTRACT**

As the largest carbon reservoir in terrestrial ecosystems, soil plays a crucial role in the global carbon cycle. Among its processes, soil organic carbon (SOC) binds with iron oxides (Fe) through chelation, aggregation, or coprecipitation, forming a key mechanism for long-term, stable soil carbon sequestration. However, it remains unclear how different human land-use activities and increasing years of cultivation alter the binding patterns of carbon and iron in soils.Therefore, this study employs the C/Fe molar ratio to characterize the coupling patterns between soil organic carbon and iron oxides. soil profiles were collected from sequences under different land-use practices and varying cultivation durations. The study characterized the distribution patterns of C/Fe molar ratios across these sequences, elucidating how land-use practices and cultivation duration influence the binding mechanisms between organic carbon and iron oxides. This provides scientific data and theoretical foundations for understanding soil carbon-iron coupling mechanisms under human land-use impacts. The results indicate:

(1) Under different land use types, compared to undisturbed buried ancient laterite (ranging from 0.09 to 0.57), the C/Fe molar ratio increased in forested land (0.19–1.90) and cultivated land (0.08–0.75), while it slightly decreased in sparse woodland and grassland (0.06–0.53) and grassland (0.07–0.44). Furthermore, the C/Fe molar ratio in the topsoil layer was significantly higher than that in the subsoil layer.

(2) Under different cultivation durations, compared to undisturbed buried ancient laterite (0.024–0.057), the C/Fe molar ratio decreased in ancient laterite cultivated for 5 years (0.022–0.027), while those of ancient laterite cultivated for 80 years and 400 years showed slight increases (ranging from 0.027 to 0.059 and 0.028 to 0.070, respectively), exhibiting a trend of initial decrease followed by increase over time.

(3) In summary, under different land use regimes, forested and cultivated soils exhibit stronger adsorption-based binding mechanisms. Specifically, the carbon-iron binding mode in forested surface soils transitions to a combined adsorption and coprecipitation mechanism, while open woodlands with weeds and weed-dominated areas demonstrate weaker adsorption-based binding. Across different cultivation durations, ancient laterite soils cultivated for 400 years and those cultivated for 80 years exhibited stronger adsorption intensity than those cultivated for 5 years. Human land use activities caused fluctuations in the adsorption strength of cultivated land, but the carbon-iron binding mode remained predominantly adsorptive.

## ABSTRACT

Biomarkers are biogenic compounds widely used to trace the origin, composition, and stabilization of soil organic carbon (SOC). Among them, lignin phenols (LGs) and amino sugars (ASs) are commonly applied as indicators of plant- and microbial-derived C, respectively. However, selective transformation and preservation of these biomarkers can decouple their abundance from original source inputs, thereby constraining their quantitative interpretation. A mechanistic understanding of the factors governing the stabilization of LGs and ASs is therefore essential for their robust application in SOC research. To address this knowledge gap, we analyzed cropland soils from East China to investigate the selective preservation of LGs and ASs and to identify their dominant controlling factors.

Both LG and AS concentrations were positively correlated with SOC contents, whereas LG:SOC ratios declined with increasing SOC. Variation in LG:SOC ratios was primarily associated with lignin molecular composition and functional group characteristics, indicating that intrinsic molecular properties regulate LG persistence. In contrast, AS:SOC ratios were strongly governed by non-crystalline minerals, highlighting the dominant role of mineral protection in the stabilization of microbial necromass. Climate variables, including annual precipitation, mean temperature, and their seasonality, emerged as primary controls of AS:SOC ratios, likely through indirect regulation of non-crystalline mineral formation. These findings highlight the molecular control of LGs and climate-mineral regulation of ASs.

These divergent stabilization controls indicate that LGs predominantly reflect relatively recent plant inputs whose retention depends on molecular traits, whereas ASs trace long-term stabilization of mineral-associated microbial C. Recognition of these contrasting stabilization pathways is essential for the prudent quantitative estimation of plant- and microbial-derived SOC using the two biomarkers.

*matheustoloto@ipb.pt

**ABSTRACT**

Mediterranean agroecosystems are characterized by high vulnerability of soil organic carbon (SOC) due to shallow profiles, intense mineralization, and increasing climatic stress. While organic amendments are widely promoted to enhance SOC stocks, the mechanisms governing short-term carbon stabilization across soil matrix remain insufficiently understood, particularly in perennial systems established on Leptosols.

This study evaluates three consecutive years of SOC dynamics following the application of olive pomace compost as a nature-based solution in a traditionally managed olive grove (Olea europaea L.) in northeastern Portugal. Compost was applied at increasing rates (0, 10, 20, and 40 t $ha^{-1}$), and SOC responses were assessed through a molecular–physical framework integrating bulk SOC, density-based fractionation into free particulate organic matter (fPOM), occluded particulate organic matter (oPOM), and mineral-associated organic matter (MAOM), together with aggregate stability measurements and soil chemical characterization.

Results demonstrate a clear dose-dependent increase in SOC, with the highest application rate sustaining carbon accumulation over the three-year monitoring period. Fractionation analyses indicate that initial SOC gains were dominated by increases in particulate pools (fPOM and oPOM), reflecting rapid incorporation of compost-derived carbon, presenting a 17.11 g $kg^{-1}$ on year 1 of monitoring, with a further decrease to 8.69 g $kg^{-1}$ on year 3 at the highest application dosage, while control group presented an standardized average of 7.65 g $kg^{-1}$. However, over time, a progressive redistribution of carbon towards the MAOM fraction was observed, specially at high dose of compost application, a relative value of 43.7 % on first year followed by 46.4 % and 55.7 % of MAOM, respectively for year 2 and 3, suggests an early shift transition from labile carbon inputs to physically and chemically protected SOC pools, even within the short-term timeframe. Furthermore, aggregate stability results suggest that physical occlusion within aggregates followed by enhanced cation exchange capacity and base saturation indicates that compost-derived organic ligands promoted stronger associations between organic compounds and mineral surfaces, reinforcing MAOM formation.

Overall, the findings demonstrate that olive pomace compost contributes to SOC stabilization through coupled biochemical and physical mechanisms, rather than solely by carbon input. This study provides field-based evidence that short-term organic amendment strategies can initiate stabilization pathways in Mediterranean Leptosols, highlighting the relevance of aggregate-mediated protection for sustaining soil carbon under climate-vulnerable conditions.

# Into the Unknown: A Continental Exploration of Viral Diversity in Australian Soils

Peipei Xue[1], Mingming Du[1], Budiman Minasny[1], Edward Holmes[2], Alex McBratney[1],

**ABSTRACT**

Soil viruses play a pivotal role in regulating microbial population dynamics and metabolic activities, thereby influencing carbon, nutrient, and biochemical cycling within terrestrial ecosystems. Despite being the most abundant biological entities on Earth, soil viruses remain poorly characterised. To address this knowledge gap, we conducted the first continental-scale investigation of soil viromes across Australia. Topsoil samples (0–10 cm) were collected within the 500–600 mm annual rainfall zone using a paired sampling design that compared land-use types within the same soil classification. Sampling spanned three major transects: (1) a South–North transect along the east coast (36.58° S–21.01° S), (2) an East–West transect across northern Australia (146.04° E–121.93° E), and (3) a 1,200 km transect across agricultural landscapes in the southwest. Whole-genome metagenomic sequencing revealed that DNA viral reads constituted less than 1% of total sequences but exhibited strong spatial heterogeneity across the continent. We identified a high diversity of novel viral taxa, with phages accounting for approximately 80% of viral sequences and Lenarviricota emerging as a dominant microbe-associated lineage. Integration of viral, bacterial, and fungal datasets indicated that soil viruses exert substantial regulatory control over microbial communities, potentially influencing ecosystem functioning. This study establishes the first continental-scale baseline of soil viral diversity and distribution in Australia, providing crucial insights into viral ecology and a foundation for predicting the impacts of soil viruses on ecosystem health and agricultural sustainability.

# Biogeographic patterns and drivers of soil viromes

**Bin Ma[1*], Yiling Wang[1], and Jianming Xu[1]**

*[1] Institute of Soil and Water Resources and Environmental Science, College of Environmental and Resource Sciences, Zhejiang University, Hangzhou, 310058, China* *E-mail Address of Presenting Author

**ABSTRACT**

Viruses are key mediators of soil microbial function and are an important component of soil ecosystems, yet existing studies of soil viromes are limited in spatial scale and biome coverage. Here, we present a comprehensive synthesis of soil virome biogeographic patterns based on the Global Soil Virome dataset (GSV) retrieved from 1,824 soil metagenomes across the globe. The GSV comprises 80,750 partial genomes of DNA viruses, of which 96.7% are taxonomically unassigned. The biogeography of soil viral diversity and community structure vary across different biomes. Interestingly, the diversity of viruses does not align with the diversity of microbial community, particularly showing low levels in forest and shrubland soils. We demonstrated that soil texture and moisture conditions are the primary factors that differentiate soil viral diversity. This is further supported by our predicted soil viral diversity atlas, which reveals higher diversity in humid and subhumid regions. Additionally, binomial degree distribution pattern suggests a random co-occurrence pattern of soil viruses. These findings provide a valuable resource for elucidating the ecology of soil viral communities and are crucial for their comprehensively incorporation into soil ecosystem models.

# Rhizosphere-triggered viral lysogeny mediates microbial metabolic reprogramming to enhance arsenic oxidation

**Xinwei Song[1,2]*, Jianming Xu[1,2] & Bin Ma[1,2]**

[1] *State Key Laboratory of Soil Pollution Control and Safety, Zhejiang University, Hangzhou, 310058, China*

*E-mail Address of Presenting Author

**ABSTRACT**

The rhizosphere is a critical hotspot for metabolic activities involving arsenic (As). While recent studies indicate many functions for soil viruses, much remains overlooked regarding their quantitative impact on rhizosphere processes. Here, we analyze time-series metagenomes of rice (*Oryza sativa* L.) rhizosphere and bulk soil to explore how viruses mediate rhizosphere As biogeochemistry. We observe the rhizosphere favors lysogeny in viruses associated with As-oxidizing microbes, with a positive correlation between As oxidation and the prevalence of these microbial hosts. Moreover, results demonstrate these lysogenic viruses enrich both As oxidation and phosphorus co-metabolism genes and mediated horizontal gene transfers (HGTs) of As oxidases. *In silico* simulation with genome-scale metabolic models (GEMs) and *in vitro* validation with experiments estimate that rhizosphere lysogenic viruses contribute up to 25% of microbial As oxidation. These findings enhance our comprehension of the plant-microbiome-virome interplay and highlight the potential of rhizosphere viruses for improving soil health in sustainable agriculture.

# Twenty-Year Time Series Reveals Ecological and Evolutionary Dynamics of Viruses in a Freshwater Lake

**Zhichao Zhou**[1*]

[1] *Institute for Advance Study, Shenzhen University, Shenzhen, China*

*zczhou2017@szu.edu.cn

**ABSTRACT**

This study leveraged 20 years of monitoring data from Lake Mendota to investigate viral ecological and evolutionary dynamics using metagenomic and metatranscriptomic analyses. Over 1.3 million viral genomes were analyzed to reveal patterns driven by temporal, seasonal, and environmental changes. More than 140,000 viral auxiliary metabolic genes (AMGs), involved in carbon, nitrogen, and sulfur cycling, were identified across a broad range of functional categories. High-abundance AMGs such as *psbA*, *pmoC*, and *katG* showed stable distributions and displayed two distinct patterns: "broad host" and "narrow host". Broad host AMGs, less influenced by environmental variability, were involved in sulfur metabolism and folate synthesis, while narrow host AMGs targeted specific host functions—for example, photosynthesis gene *psbA* in cyanophages, and *gnd* and *zwf* related to the pentose phosphate pathway. The study uncovered correlations between virus-host interactions and seasonal changes, along with ecological niche differentiation. High-frequency viral populations exhibited both gene-specific and genome-wide selection. This included positive selection of adaptive genes, temporal reduction in genome-wide SNP heterogeneity, and the emergence of dominant subpopulations with enhanced replication and transcriptional regulation capacities. These dominant viruses—termed “royal family” viruses—maintain ecological stability and dominance through genomic evolution, consistent with the "kill-the-winner" model. Additionally, viral abundance was linked to environmental variables such as inorganic carbon and ammonium, highlighting complex interactions between nutrient availability and predator-prey dynamics.

## ABSTRACT

Soil viruses are increasingly recognized as key agents in biogeochemical cycling, yet their evolutionary dynamics and regulatory roles under long-term environmental acidification remain poorly understood. Using an integrated approach that combines $D_2O$-labeled Raman spectroscopy, $^{15}N$ isotope tracing, metagenomic sequencing, and machine learning models on 18-year acidified soils, we demonstrate how virus-host co-evolution shapes $N_2O$ emissions. Our results reveal that long-term acidification drives convergent evolutionary trajectories in both denitrifiers and viruses, characterized by genomic streamlining and functional specialization. While microbial hosts transitioned to stress tolerance life history strategies, viruses evolved enhanced regulatory capacity through specialized gene arsenals and morphological adaptations. Machine learning modeling identified host defense capacity as the primary driver of virus-denitrifier interaction outcomes, facilitating viral pruning that optimizes denitrifying community structure. Crucially, virus addition experiments uncovered a previously unrecognized dual regulatory mechanism: while neutral soils exhibited a conventional 'quantity-driven' mode through increased *nosZ* gene (nitrous oxide reducing gene) abundance, acidic soils displayed a novel 'efficiency-optimization' mode that enhanced $N_2O$ reductase activity by 33.2% without altering genetic potential. Our study establishes viruses as co-evolutionary partners that develop sophisticated regulatory mechanisms under persistent environmental stress, offering novel insights for managing $N_2O$ emissions in acidified soils.

# Soil viruses as key regulators of carbon sequestration and plant growth

**Yongfeng Wang[1*], Xiaolong Liang[1]**

*[1] CAS Key Laboratory of Forest Ecology and Silviculture, Institute of Applied Ecology, Chinese Academy of Sciences, Shenyang, China*

*E-mail: yfwang@iae.ac.cn

**ABSTRACT**

Soil viruses are increasingly recognized as pivotal agents in terrestrial biogeochemical cycles; however, their context-dependent roles in modulating soil organic carbon (SOC) dynamics remain inadequately characterized. Through integrated lab- and field-scale experiments, we investigated how environmental cues influence viral life-history strategies, specifically, the transition between lytic and lysogenic cycles, and their consequent effects on microbial turnover, nutrient cycling, and carbon sequestration. Our findings reveal that viral life-history strategies are highly responsive to environmental conditions. Nutrient-rich environments, such as those amended with long-term manure or labile carbon inputs, promote lytic dominance. This shift accelerates microbial turnover and necromass accumulation via the "viral shunt," whereby host cell lysis releases labile nutrients, including dissolved organic carbon (DOC) and nitrate. These nutrients not only stimulate the enrichment of fast-growing bacterial taxa but also enhance plant growth, as demonstrated in soybean rhizosphere experiments in which prophage induction with mitomycin C significantly boosted root development. Beyond immediate nutrient release, viral activities exert broad ecological influence. Microcosm studies involving direct manipulation of viral abundance revealed that viral predation restructures microbial communities and alters their functional gene profiles, thereby reducing $CO_2$ and $N_2O$ emissions. More importantly, this top-down control enhances microbial carbon use efficiency and accelerates community turnover, resulting in substantial accumulation of microbial necromass. These virus-mediated processes are strongly context-dependent. While lytic activity may elevate $CO_2$ emissions in SOC-poor soils, it promotes necromass stabilization and SOC accrual in organically enriched environments. Under nutrient-limited or drought-stressed conditions, the lysogenic viruses and viral auxiliary metabolic genes (AMGs) become enriched, suggesting a "metabolic rescue" strategy that supports host persistence under stress. An emerging virus-mediated microbial carbon pump (MCP) framework connects these dynamics, highlighting viral lysis and AMG-driven metabolic reprogramming as key mechanisms underlying SOC persistence. Together, our results position soil viruses as central regulators of carbon cycling, linking microbial mortality to both plant vitality and long-term soil carbon storage. These insights underscore the potential of leveraging viral community dynamics through targeted organic amendments to achieve climate-resilient soil management.

# Microbial Community Succession in the Rhizosphere of Citrus Grandis Exocarpium in Response to Fertilization and Huanglongbing Stress

## ABSTRACT

**Overview:** *Candidatus Liberibacter* asiaticus (CLas) is the causative agent of Huanglongbing (HLB), a deadly disease that affects citrus output globally. Although the rhizosphere microbiome is essential for plant health and disease resistance, little is known about how long-term fertilization controls microbiome assembly in medicinal citrus root and soil compartments and how this is related to the occurrence of HLB. Few studies have combined multi-year, multi-compartment microbiome dynamics with host metabolomics and pathogen response in citrus, despite earlier research highlighting the general advantages of organic fertilizers (OF) on soil microbial diversity and plant growth.

**Method:** We investigated the bacterial and fungal communities in the bulk soil, rhizosphere, and endosphere of *Citrus Grandis Exocarpium* (Huajuhong) after 1, 3, and 5 years of continuous OF or chemical fertilizer (CF) application using amplicon sequencing and co-occurrence network analysis. Metabolomic analysis assessed subsequent effects on plant medicinal quality (Fig. 1).

**Result:** OF enhanced microbial α-diversity and network stability. Bacterial communities dominated network interactions and showed clear temporal succession, with OF enriching beneficial taxa like *Burkholderia*, while CF reduced pathogenic *Fusarium* abundance. Surface soils showed higher network complexity, indicating functional stratification along soil depth. The highest CLas infection was in 5-year trees, indicating prolonged HLB stress impaired the endophytic microbiome—an effect mitigated under OF. Metabolomics revealed OF broadened the spectrum of bioactive compounds, whereas CF elevated specific flavonoids and polysaccharides.

**Discussion:** Our findings demonstrate that fertilization regimes drive distinct successional trajectories in the rhizosphere microbiome. Under HLB stress, plants become more susceptible to secondary infections. Although OF promotes a stable and diverse microbiome, associated risks such as antibiotic resistance genes warrant careful assessment. This study offers a microecological foundation for designing integrated fertilization and probiotic strategies to enhance systemic disease resistance in citrus.

**ABSTRACT**

Prophages integrated within prokaryotic genomes are key drivers of microbial community dynamics. However, current methods such as (viral) metagenomics, metatranscriptomics, and induction assays cannot capture active translation *in situ*, the critical step that reflects direct metabolic investment. Here, we apply metaRiboSeq, i.e. metatranslatomics, to quantify how prokaryotes allocate translational resources to their prophages at the community level across diverse microbiome types. We recovered metagenome-assembled genomes (MAGs) from soil, marine, and human samples, representing free-living and host-associated environments. By mapping ribosome-protected mRNA fragments to prophage regions within MAGs, we quantified what fraction of host translational activity is devoted to prophage genes, and how that investment is distributed among lysogeny maintenance, lytic, and auxiliary metabolic genes. We hypothesize that prophage translational burden and investment strategies differ across ecosystems, reflecting variation in environmental conditions. Thus, metaRiboSeq is a powerful tool for resolving phage translational activity *in situ* and provides a quantitative framework for understanding how prokaryotes allocate resources to their prophages.

**ABSTRACT**

Constructed wetlands (CWs) are widely used as a sustainable technology for wastewater treatment, yet the role of viruses within their microbial communities remains largely unexplored. In this study, two pilot-scale horizontal subsurface flow CWs were established to examine viral community dynamics under different hydraulic loading rates (HLRs), using in-depth metagenomic analysis. Gene-sharing network analysis revealed that CWs harbor a high proportion of novel viral lineages, with over 99% of viral operational taxonomic units not clustering with known References genomes. Notably, a subset of core viruses, dominated by families such as *Siphoviridae* and *Podoviridae*, persisted across different compartments and conditions, suggesting their potential ecological importance. HLR significantly influenced the assembly of viral communities, with higher diversity and niche breadth observed under elevated HLR conditions, particularly in the substrate layer. Similar dynamics between viral and prokaryotic communities were identified, indicating coordinated responses to hydrological variations. Importantly, viruses were found to interact closely with functional prokaryotes involved in key nutrient-cycling processes. Through CRISPR-based host prediction, we demonstrated that viruses could infect microorganisms responsible for denitrification and ammonia oxidation. Furthermore, viral auxiliary metabolic genes (AMGs) associated with sulfur and nitrogen cycling were detected, with sulfur-related AMGs notably enriched under higher HLR. These findings reveal the significance of viruses in pollutant removal in CWs and enhance the understanding of the relationship between engineering design parameters and performance from microbial perspectives.

## ABSTRACT

Viruses are ubiquitous regulators of microbial dynamics and may thus greatly influence global microbial- driven greenhouse gas emissions. Anthropogenic stressors, such as chemical contamination, are likely to amplify these viral contributions; however, their global significance and underlying mechanisms remain elusive. Utilizing $^{15}N$ tracing, metagenomics, and laboratory assays, we explore soil viral communities and their evolutionary potential under the stress from antibiotic ciprofloxacin (CIP), focusing on their roles in regulating nitrogen cycling and $N_2O$ production. Through isolation and reinoculation of soil viruses, we demonstrate that CIP stimulates soil denitrification- derived $N_2O$ production, with 18 to 29% of the increase attributed to viral activity. Under CIP stress, soil viruses shift toward a lysogenic lifestyle, promoting mutualism with denitrifiers by horizontally transferring viral denitrification- related auxiliary metabolic genes (AMGs). The observed synonymous mutations in these AMGs, driven by CIP, suggest enhanced purifying selection, likely optimizing codon usage to align with host pReferences. This optimization likely enhances the expression of denitrifying AMGs and increases $N_2O$ production. This study provides insights into the overlooked role of viral dynamics and genomic mutations in modulating $N_2O$ production under stressful environments, highlighting their evolutionary significance and impact on biogeochemical cycles in the Anthropocene.

## ABSTRACT

**[Objective]** The distinctive symbiotic relationship between rhizobacteria and soybean (Glycine max) can enhance soil fertility and assist soybean defense heavy metal stress, such as cadmium (Cd), in soils. Soil viruses are critical for modulating microbial activities and enhancing host adaptability to soil contamination by encoding auxiliary metabolic genes (AMGs). However, the community structure, functional diversity and ecological roles of soil viruses and their dynamic interactions with soil-dwelling microbes under Cd stress remain unclear. Here, we characterized the bulk and rhizosphere bacterial community in a Cd-contaminated soybean field at five growth stages and investigated the rhizosphere microbial functional traits and the viral community after flowering using metagenomics. We showed that the rhizosphere bacterial community exhibited a stronger soybean development- dependent diversity pattern relative to bulk soil and had a more critical role in predicting Cd accumulation. The relative abundance of Actinobacteria in the rhizosphere increased with soybean development, particularly in the families *Nocardioidaceae* and *Intrasporangiaceae*, which were further identified as the main contributors of amino acid transport E and secondary metabolites Q genes. Viral analysis suggested an interactive and complementary assembly between viral and bacterial communities. Importantly, viruses exhibited a broader host range during the flowering period, and infected specific functional taxa such as *Bradyrhizobium* and *Nocardioides*, highlighting their potential impact on the rhizobia-soybean symbiosis and soybean growth and fitness. Furthermore, AMGs related to element cycling and microbial metabolism were identified and functionally and phylogenetically characterized, suggesting the contribution of these virus-encoded genes to biogeochemical cycles and soybean fitness under Cd stress. Together, our results expand our understanding of the ecological functions of rhizosphere viruses in Cd pollution-stressed soils, and provide insights in developing new strategies for bioremediation of contaminated soils.

**ABSTRACT**

Rare earth element (REE) mining causes severe soil degradation and disrupts microbially mediated carbon cycling, yet the role of soil viruses during ecosystem recovery remains largely unexplored. Here, we investigated how long-term revegetation reshapes soil viromes and regulates microbial carbon processing in REE tailings. Using an eight-year vegetation restoration chronosequence, we combined 16S rRNA amplicon sequencing, shotgun metagenomics, viral genome reconstruction, virus–host linkage analyses, and structural equation modeling to elucidate virus-mediated mechanisms underlying soil recovery.

Vegetation restoration markedly improved soil quality, increasing organic carbon, nutrient availability, microbial biomass, and extracellular enzyme activities. Concomitantly, viral communities exhibited higher diversity and a pronounced shift from lysogenic to lytic lifestyles. Viral community composition closely tracked bacterial community succession, and virus–host associations revealed active viral control over dominant bacterial taxa involved in complex carbon degradation. Lysogenic viruses in unrestored tailings encoded diverse auxiliary metabolic genes (AMGs) related to carbohydrate, amino acid, and energy metabolism, whereas AMG abundance declined with increasing soil quality, indicating reduced viral metabolic supplementation under nutrient-rich conditions.

Partial least-squares path modeling identified viral life-strategy transitions as a central mechanistic bridge linking revegetation to soil quality enhancement. Vegetation-driven nutrient enrichment induced a lysogenic-to-lytic switch, strengthening top-down viral regulation of bacterial communities and stimulating extracellular enzyme activities. This process enhanced microbial turnover and carbon processing through a soil “viral shunt,” whereby viral lysis releases microbial biomass and intracellular substrates that fuel heterotrophic decomposition.

Our findings demonstrate that soil viruses act as keystone regulators coupling aboveground revegetation with belowground carbon cycling during REE tailings restoration. By integrating viral dynamics into restoration ecology, this study extends the viral shunt concept to terrestrial reclamation systems and highlights soil viromes as critical, yet overlooked, drivers of ecosystem recovery.

**ABSTRACT**

Soil viruses are highly abundant and serve as key modulators of microbial population dynamics and soil ecological processes. Anthropogenic environmental changes, including those driven by climate and land use, are reshaping soil ecosystems; however, their impact on the often-overlooked soil virome remains poorly understood. In this study, a field mesocosm experiment was used to investigate the influence of a warmer, drier climate regime—including its legacy effects—on soil viral communities under contrasting fertilization treatments (manure vs. urea). Results showed that both warming and fertilization significantly altered the composition of soil viral and bacterial communities. Notably, warming and fertilization substantially enriched viral-encoded auxiliary metabolic genes (AMGs) related to carbon cycling. These viral AMGs may be transferred to microbial hosts, thereby directly mediating biogeochemical cycles. Viral AMGs could modulate host metabolism during infection, potentially influencing biogeochemical cycling. Furthermore, fertilization interacted with climatic factors to regulate the abundance of specific viral taxa and shape host-virus interaction networks. Collectively, these findings provide novel insights into the shaping of soil viromes by climate change and underscore the significant ecological roles of viruses in influencing host dynamics and biogeochemical cycling.

# How do soil viruses exert impacts on the soil carbon cycle under anaerobic? The ubiquitous but neglected part

**Di Tong[1*] and Jianming Xu[1]**

[1] *College of Environmental and Resource Sciences, Zhejiang University, Hangzhou 310058, China*

*E-mail Address of Presenting Author: tongdi@zju.edu.cn

**ABSTRACT**

Anaerobic oxidation of methane (AOM) has the potential to mitigate global warming by converting $CH_4$ either to $CO_2$ or to soil organic carbon (SOC) stored in soils. However, it remains unclear whether soil viruses affect the AOM process and carbon sequestration. In addition, viruses have two major life cycle states (i.e. lytic and lysogenic) that can differentially reprogramme the host metabolism. How and to what extent viruses in different life states influence the AOM process remains elusive. To address this knowledge gap, we used $^{13}C$ tracing to compare the effects of mitomycin C-induced and free extracellular viruses on anaerobic methane oxidation. In this study, we first demonstrated that the inoculation of mitomycin C-induced viruses functioned as prophages, resulting in distinct effects on AOM compared to free extracellular viruses. Specifically, both mitomycin C-induced and free extracellular viruses enhanced $CH_4$-derived carbon sequestration in soil. However, the free extracellular viruses could increase 60.42 Mg SOC and 8.58 Mg Fe-bound organic C $d^{-1}$ globally through viral lysis and increase carbon affinities to iron oxides. The mitomycin C-induced viruses could increase the daily amount of 28.5 Mg SOC, but decrease 19.6 Mg Fe-bound organic C globally, by improving the survival of associated microbes to promote the AOM process. This work demonstrates for the first time that inoculation with mitomycin C-induced viruses provides a novel approach to directly quantify the effects of lysogenic cycle viruses on soil functions and the contributions of viruses in two different life cycles, lytic and lysogenic, to soil carbon sequestration under anaerobic conditions. These results complement the 'viral shuttle' mechanism in soils and provide a new understanding of the impact of viruses on soil carbon sequestration.

*E-mail Address of Presenting Author: niemin@issas.ac.cn

**ABSTRACT**

Against the backdrop of intensive agricultural production, continuous monocropping readily induces a suite of replant obstacles, which represent a critical limiting factor for both the yield and quality of crops. In the cultivation of peanut (*Arachis hypogaea* L.), one of China's foremost oil and economic crops, continuous cropping phenomenon are prevalent nationwide. The high incidence of soil-borne diseases is a defining hallmark, especially the occurrence of bacterial wilt—a globally important plant disease caused by *Ralstonia solanacearum*.

Crop rotation is promoted widely as a sustainable solution to alleviate replant obstacles, with resulting benefits to crop health and yield. The enhanced disease suppression capacity of crop rotation has been attributed to the modulation of rhizosphere bacterial community. As highly abundant biological entities in soil, viruses especially phages (viruses of infecting bacteria) have been shown to drive changes in the diversity and composition of bacterial community. Leveraging phage—bacteria host interactions, phages exert a vital regulatory in biogeochemical cycles and are also believed to be applicable to control soil-borne bacterial diseases. However, it remains unclear whether rhizosphere phage communities are involved in rotation-mediated disease suppressiveness, and determining phage—bacteria interactions is crucial for establishing a holistic understanding of rhizosphere microbiome functions.

Based on a 12-year long-term field experiment, coupled with multiomics analysis, we investigated how responses of rhizosphere phages to crop management impacted soil disease suppressiveness. Our results showed that rotation assists peanut to resist bacterial wilt disease by reducing pathogen abundance and constructing beneficial rhizosphere microbial communities, as a consequence of the phage–bacteria synergistic interactions. Phage communities in monocropping and rotation rhizosphere were dominated by phages of potentially beneficial genera and phages of putative pathogens, respectively, with the relative abundance of *Ralstiona*-targeted phages being much higher in rotation rhizosphere (18.05%) than in monocropping rhizosphere (2.83%). The regulation of bacterial communities by phages were also verified by the phage transplantation experiment. Collectively, our findings suggest that crop rotation can serve as a strategy for sustainable agriculture by modulating rhizosphere phage–host interactions to enhance disease suppressiveness.

# Extracellular polymeric substances in soil: drivers, functionality and future research directions

**Cordula Vogel**[1]

[1] *Institute of Soil Science and Site Ecology, TU Dresden, Dresden, Germany*

**ABSTRACT**

Most microorganisms on Earth are suggested to surround themselves in a matrix of extracellular polymeric substances (EPS). This EPS matrix fulfils crucial functions for microbial life, such as mitigating environmental stress. Soil microorganisms have a central role in global biogeochemical cycles, and their residues contribute to soil organic carbon. However, despite the central role of microorganisms, the contribution of EPS to these processes and its fate in the soil are still being investigated. It is known that EPS can exhibit properties such as high-water absorption and viscosity, raising questions about its potential applications in agriculture. Yet, our knowledge of drivers, functionality and overall significance of EPS in soil remains still limited.

At the conference, I will share insights from various experiments and field studies conducted in different ecosystems. These studies address the question of how environmental factors influence the composition of EPS. I will also present studies on the potential functionalities of EPS. Furthermore, I will present results from a visualisation approach that quantifies the formation of biofilms within the porous soil network, offering directions for future research. Overall, I will provide a compelling insight into EPS within soil systems and shed light on its potential role in agriculture. This will provide a foundation for discussions about functional significance and ecological relevance, as well as future research directions aimed at improving our understanding of EPS in soil and possible applications.

# Small fractions, large effects: the role of extracellular polymeric substances in soil function

**Marc Redmile-Gordon** [1]

[1]*Dept. of Environmental Horticulture, The Royal Horticultural Society, Wisley, Surrey, GU23 6QB, UK*

**ABSTRACT**

Most microorganisms are thought to embed themselves within a matrix of extracellular polymeric substances (EPS). Although EPS can represent only a small, transient fraction of total soil organic matter at any given moment, it can exert outsized control over soil function by regulating micro-scale hydration, adhesion, and biofilm formation. These EPS-mediated processes can, in turn, influence aggregate stability, pore-scale connectivity, diffusion of gases and solutes, and the spatial coupling of microbes with substrates and mineral surfaces. Yet, linking EPS chemistry and physical properties to measurable soil functions remains challenging because EPS is heterogeneous, highly reactive, and difficult to quantify in situ across relevant spatial and temporal scales. In this presentation, I will examine why "small fractions" of EPS can produce "large effects" on soil physical, chemical, and biological functioning. The talk will synthesize current understanding of (i) environmental and management drivers that modulate EPS production and composition, (ii) mechanistic pathways through which EPS alters water retention, viscosity, and soil structural dynamics, and (iii) implications for nutrient cycling and carbon persistence via interactions with minerals and aggregates. I will conclude by outlining methodological and conceptual priorities—particularly approaches that connect pore-scale EPS organization and biofilm architecture to whole-soil performance—aimed at improving predictive understanding of EPS in soils and informing practical strategies to enhance soil resilience under agricultural use.

# Seeing the Invisible: Visualizing Enzymatic Processes in Soil Hotspots

**Nataliya Bilyera[1*], Yakov Kuzyakov[2], Callum C. Banfield[1] and Michaela A. Dippold[1]**

[1] *Geo-Biosphere Interactions, Department of Geosciences, University of Tuebingen, 72076 Tübingen, Germany*

[2] *Department of Soil Science of Temperate Ecosystems, University of Goettingen, 37077 Göttingen, Germany*

*Email: nataliya.bilyera@uni-tuebingen.de

**ABSTRACT**

Exoenzymes in the soil are crucial to mobilize nutrients, transform pollutants, and maintain soil health. Understanding the spatial and temporal organization, as well as the intensity of biochemical processes in soil hotspots, is essential to unravel soil functioning and nutrient cycling. However, this remains difficult for direct observation.

Soil zymography (Spohn et al., 2013) represents a non-invasive method facilitating the *in situ* visualization and localization of potential enzyme activities in soil. Because of its universality and simplicity, soil zymography imaging has been widely used to visualize the hidden microbial and root life in soil, which is a very heterogeneous and "dark" environment. Our primary focus is to highlight the progress made over last 10 years with respect to the spectrum of enzyme activity imaging, zymography resolution, standardization and hotspot identification (Bilyera and Kuzyakov, 2024). We emphasize the integration of zymography with the visualization of soil acidification (optodes), root exudation and pesticides ($^{14}$C phosphor imaging), fertilizers ($^{33}$P phosphor imaging), nutrients (DGT) and water (neutron imaging) fluxes.

As processes and mechanisms are clearly multifactorial, combining individual approaches is essential to achieve a comprehensive understanding of soil processes. The multi-imaging approach comes with a set of challenges: 1) bridging scales in time (from minutes to days) and space (from µm to cm); and 2) the sequence of method application. The co-localization analysis of such individual images integrates biochemical, physico-chemical and microbial properties, which facilitate a deeper understanding of soil processes and microbial interactions (Banfield et al., 2017; Bilyera et al., 2021).

We present the advancements made in soil zymography, as well as its current applications, challenges and potential integration with other imaging methods. This versatile technique has applications in natural and agricultural ecosystems, in both field settings and laboratory studies, capable of scaling from the entire root system (cm and dm) down to microbial communities (µm).

**ABSTRACT**

Microbial-derived carbon plays a crucial role in mitigating climate change by forming stable carbon components through the soil microbial carbon pump. However, previous studies usually used intracellular carbon (microbial necromass carbon) as a quantitative indicator, ignoring the contribution of extracellular carbon (EPS) as an extracellular metabolite of microorganisms to soil organic carbon (SOC), particularly in deep soils. This study explored the distribution of EPS in six typical soil profiles (0–120 cm) from two parent materials (limestone and shale) and three land use types (dryland, woodland, and paddy land). The contribution of microbial biomass carbon (MBC) to SOC was significantly higher than that of EPS-carbon (EPS-C) in surface soils (0–40 cm), while EPS-C constituted a larger proportion in deeper soils (80–120 cm). The EPS accumulation efficiency (EPS-protein/MBC and EPS-polysaccharide/MBC) gradually increased with soil depth. This accumulation was strongly correlated with the abundance of g_Zixibacteria, g_Zavarzinella, g_Xylohypha, g_Xanthothecium, and g_Xanthagaricus. Data analysis revealed that β-glucosidase (BG) activity and total nitrogen (TN) content had significant negative effects on the EPS/SOC ratio. Additionally, extracellular enzyme analyses confirmed that low nitrogen availability in deeper soils enhanced the EPS accumulation efficiency, thereby increasing the EPS-C/SOC ratio along the soil profile. Overall, this study provides new insights into the composition of deep soil carbon pools and highlights the important role of EPS in deep soil carbon storage.

## ABSTRACT

Soil extracellular polysaccharides (EPSac) are important biopolymers in terrestrial ecosystems, playing key roles in soil aggregation, water retention, nutrient cycling, and carbon sequestration. These polysaccharides are produced by a wide range of organisms, including archaea, bacteria, fungi, plants, and soil fauna. However, their complex composition and yet largely unknown abundance in environmental samples present significant challenges for their identification and quantification.

In this study, we cultured and collected EPSac samples from various organisms across a wide range of phyla belonging to archaea, bacteria, fungi, algae, higher plants, and soil fauna. The extraction methods were tailored to specific biological sample types, such as cation exchange resin extraction for microbial cells and water extraction for plant roots and soil fauna. Dissolved extracellular polysaccharides are purified from low molecular weight metabolites using ultrafiltration or precipitation prior to biochemical analysis. Plant samples will be cultivated hydroponically from seeds to minimize soil and microbial contamination of fine roots. To identify and quantify the monomeric composition of the polymers, we will employ an optimized acid hydrolysis method in combination with 1-phenyl-3-methyl-5-pyrazolone (PMP) derivatization, followed by analysis using ultra-high-performance liquid chromatography with high-resolution Orbitrap mass spectrometry (UPLC-Orbitrap MS).

EPSac-specific monomers will be seeked for that do not occur in other known cell wall-based and/or storage polysaccharides of prokaryotes and eukaryotes. To strengthen biological source attribution of EPSac, we will integrate their monomeric signatures with genomic information on EPS biosynthesis potential across representative taxa. By comparing detected monosaccharide profiles with lineage-specific biosynthetic capacities inferred from annotated EPS gene clusters, we aim to generate probabilistic links between chemical features and their likely biological origins. In parallel, machine-learning approaches such as random forest modeling, complemented by indicator species analysis, will be used to identify robust chemical and genomic biomarkers that distinguish EPSac produced by different organisms. These integrated biomarkers will then be applied to complex soil communities to infer the relative contributions of various taxes to soil EPS pools. Together, this chemical–genomic–computational framework provides a rigorous yet flexible strategy for tracing EPSac quantities and origins in soils and study their effect on soil physicochemical properties and soil biogeochemical processes.

**ABSTRACT**

Coastal regions face significant agricultural challenges due to soil salinization. Soil aggregates, serving as the fundamental architectural units of the soil matrix, are crucial for maintaining soil fertility, structural integrity, and ecosystem multifunctionality. Through field investigations and sampling within 20-30 km of the coastline, this study explores the complex interactions among microorganisms in saline-alkali soils and the mechanisms behind their synergistic remediation effects. Our results indicate that increasing soil salinity and exchangeable sodium percentage significantly reduced aggregate indices (mean weight diameter (MWD), R250) and soil organic carbon (SOC). Fungal α diversity decreased with salinity, whereas bacterial alpha diversity increased. Microbial communities structure diverged significantly under varying stress levels: bacterial and protistan communities were primarily driven by electrical conductivity (EC) and SOC, while fungal community structure was influenced by pH and soluble sodium. With intensifying stress, the ecological networks of both dominant and rare taxa became more complex, marked by significant increases in nodes, edges, network density, and average degree, alongside decreased modularity and the proportion of cross-domain connections. *Mortierella* was closely associated with SOC and aggregates. Its targeted removal, compared to random nodes removal, significantly reduced the proportion of cross-domain connections, an effect exacerbated by salinity, underscoring its key role in maintaining network stability. Furthermore, exogenous inoculation with a *Mortierella* consortium (*M. elongata*, *M. alpina*, and *M. capitata*) significantly increased soil extracellular polymeric substances (uronic acids and humic acids) and enhanced the MWD of aggregates in coastal saline soil. Our findings highlihgt that *Mortierella* is a key functional taxon regulating microbial network stability and aggregate structure, providing a promising microbial resource with both theoretical and practical implications for the bioremediation of coastal saline soils.

**ABSTRACT**

Extracellular polymeric substances (EPS) constitute a significant component of soil organic matter (SOM) and play multifunctional roles in nutrient cycling, microbial survival, and soil health. However, the processes by which EPS are transformed and further retained by soil minerals remain poorly understood. This study investigated the chemical speciation of biogenic elements and mineral-SOM associations after EPS adsorption and turnover in typical clay minerals and three soils with varying mineral compositions, in order to distinguish the respective contributions of direct adsorption and microbial assimilation of EPS to SOM persistence. Synchrotron-based X-ray absorption near-edge structure (XANES) analysis revealed that incubation led to approximately twice as large changes in C and S speciation as EPS surface adsorption, suggesting stimulated microbial activity is a more important pathway for EPS to participate in SOM turnover. Incubation with EPS significantly increased carboxylic carbon by 10% while decreasing aromatics by 31% across the three studied soils. In-situ Fourier transform infrared (μ-FTIR) spectroscopy showed a 90% enhancement in Fe-organic associations (based on R2 increase) after incubation, whereas phyllosilicate-EPS associations were less stable and underwent disintegration in the Fe-rich, low-pH conditions of Mollisol and Alfisol. The differential preservation patters for various molecules arise from molecular fractionation, with carboxylic-rich compounds enriched on iron oxides and aromatic and aliphatic carbon enriched on phyllosilicates. Overall, EPS stabilizes SOM by stimulating the microbial carbon pump to assimilate native SOM and facilitating its association with iron oxides.

# Modeling the Turnover and Stabilization of Soil Extracellular Polymeric Substances (EPS)

**Xiaoyu Cheng[1], Yichao Wu[1], and Peng Cai[1*]**

[1] *State Key Laboratory of Agricultural Microbiology, College of Resources and Environment, Huazhong Agricultural University, Wuhan, China*

*chengxiaoyu@webmail.hzau.edu.cn

**ABSTRACT**

Soil organic carbon (SOC) dynamics emerge from the interplay among plant inputs, microbial transformations, and mineral protection. Extracellular polymeric substances (EPS) have been proposed as an important pathway through which microbial carbon enters stabilized soil pools.

This study aims to develop and calibrate an isotope-informed process model that explicitly represents EPS、microbial biomass carbon (MBC) and microbial cellular necromass, in order to quantify the role of EPS in routing microbial-derived carbon into long-term stabilized organic matter.

The $^{13}C$ tracer incubation experiments were conducted in which pre-incubated soils received $^{13}C$-labeled EPS and $^{13}C$-labeled cellular necromass, followed by a 50-day incubation with measurements of $^{13}CO_2$ efflux, residual soil $^{13}C$-SOC, and total $^{13}C$ recovery. The model partitions each microbial-derived pool into fast-turnover and mineral-associated fractions and uses nonlinear kinetic formulations, including Michaelis–Menten uptake for microbial assimilation. Parameter estimation followed a three-step workflow: Sobol global sensitivity screening, nonlinear least-squares optimization to obtain optimal parameter set, and Markov chain Monte Carlo (MCMC) sampling to characterize parameter uncertainty.

The model captured the observed temporal patterns of $^{13}CO_2$ mineralization and soil $^{13}C$ retention with high fidelity (RMSE≈3.1% for predicted $^{13}$SOC). A rapid initial increase in $^{13}C$-labeled MBC was followed by stabilization as substrate availability declined. Approximately 39% of the cellular necromass pool and 19% of the EPS pool were assigned to fast-turnover fractions, indicating that most EPS persists in more stabilized forms, likely through mineral interactions or physical entrapment. Steady-state analysis further showed that EPS contributes to the mineral-associated organic matter pool and thus to long-term SOC stabilization.

Including EPS as a separate carbon pool in soil carbon models helps to better understand how microorganisms affect the stability of SOC and improves the ability to predict the formation of mineral-bound organic matter.

Currently, there are limited methods for extracting EPS, uncertainties in kinetic parameters, and only a few soil types are involved. All of these indicate the need to improve quantitative methods, validate models in more soils, and link parameters with soil properties to improve the applicability of models.

# Microbial extracellular residues dominate long-term soil organic carbon storage

**ABSTRACT**

Soil microbes play a critical role in long-term soil organic carbon storage through processing of plant-derived carbon into less degradable forms and production of microbially-derived carbon during uptake of organic compounds, biosynthesis, growth and death. Although microbially-derived carbon includes both cellular and extracellular residues, and the mass of extracellular residues often exceeds microbial biomass, the contribution of cellular residues to soil carbon stocks is well established, while the role of extracellular residues is far less understood. Here we combine a continental-scale investigation with microcosm experiments and find that, contrary to prevailing concepts for soil carbon formation, microbial extracellular polymeric substances constitute the dominant soil microbial residue, and the primary source of microbially-derived carbon to the mineral associated organic carbon pool, which is less vulnerable to environmental disturbances. Our work provides new mechanistic insights into how soil microbiomes shape the fate of soil carbon and highlights the fundamental importance of microbial extracellular polymeric substances in controlling carbon sequestration under global change.

**ABSTRACT**

Soil microbial carbon partitioning is a critical regulator of soil carbon cycling, yet how resource input systematically alters intracellular versus extracellular carbon allocation and efficiency remains unclear. Here, by integrating dual-isotope labeling ($^{18}O$-$H_2O$ and $^{13}C$-glucose) with microbial community analysis, we reveal a fundamental strategy shift in carbon metabolism. Glucose addition reversed the carbon allocation pattern: extracellular polymeric substance carbon ($C_{EPS}$) was 2.62-fold higher than growth carbon ($C_{growth}$) without amendment, whereas $C_{growth}$ exceeded $C_{EPS}$ with glucose. This re-allocation coincided with a marked decline in the production efficiency of both biomass and EPS. Mechanistically, glucose elevated the dominance of r-strategists from 58% to 71%, revealing a underlying mechanism: under low nutrients, K-strategists dominate, allocating more carbon to stable EPS, whereas high nutrient availability promotes r-strategists, shifting carbon toward growth and respiration and incurring an efficiency trade-off. Our study establishes a mechanistic framework linking environmental perturbation to carbon allocation by coupling community assembly with microbial physiology, providing crucial insights for predicting soil carbon dynamics under global change.

**ABSTRACT**

Within the global carbon and nitrogen cycles, the transformation mechanisms of reactive carbon and nitrogen pools into stable pools constitute a central research topic in Earth sciences. Traditionally, this process has been regarded as primarily mediated by microorganisms, yet its conversion efficiency and stability are frequently constrained by environmental conditions. In recent years, abiotic transformation pathways—particularly the Maillard reaction (a condensation reaction between reducing sugars and amino acids widely observed in food chemistry)—have gained recognition for their potential to generate chemically stable, recalcitrant melanin-like polymers. These compounds are increasingly acknowledged as playing a crucial abiotic role in carbon and nitrogen sequestration within geological environments such as soils and sediments. Nevertheless, the mechanisms governing how this reaction is effectively driven under ambient natural conditions, including its key interfaces and catalytic pathways, remain poorly understood.

Consequently, this study proposes a core scientific hypothesis: the mineral-extracellular polymeric substance (EPS) composite interfaces, widely present in soils and sediments, constitute a natural pathway that drives efficient Maillard reactions, thereby promoting the geological polymerisation and long-term sequestration of carbon and nitrogen. EPS, as a naturally secreted microbial substrate reservoir, is rich in polysaccharides (reducing sugars) and proteins (amino acids) required for the Maillard reaction. Meanwhile, metal oxide minerals such as iron and manganese provide substantial specific surface area and abundant Lewis acid sites, serving a dual function of adsorbing and concentrating reaction substrates while catalysing key steps. Their coupling may substantially reduce the reaction energy barrier, enabling efficient carbon and nitrogen fixation under ambient temperature and pressure conditions.

To validate this hypothesis, this study designed a multi-scale experimental verification system. First, typical manganese ore (δ-$MnO_2$) and goethite (α-FeOOH) were selected as model mineral catalysts, with standard EPS extracted from activated sludge. A ‘mineral-EPS’ simulated reaction system was established and cultivated under controlled conditions of temperature (10–60°C), pH (7–8.5), and anaerobic conditions. The study comprehensively employed techniques including thermogravimetric-differential scanning calorimetry (TG-DSC), Fourier transform infrared spectroscopy (FTIR), ultraviolet-visible spectroscopy (UV-Vis), and near-edge X-ray absorption fine structure spectroscopy (NEXAFS) to systematically characterise the reaction processes and product properties. Key parameters monitored included the browning index, formation of C=N bonds, and generation of melanin-like polymeric compounds. To elucidate the transformation mechanism at the molecular level, high-resolution Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR MS) was employed to precisely analyse the evolution of molecular composition in soluble organic matter before and after the reaction.

The innovation of this study lies in its pioneering use of multi-technique corroboration to establish the mineral-EPS interface as a key site for efficient environmental Maillard reactions, revealing its catalytic polymerisation dynamics at the molecular scale. This not only positions classical abiotic chemical reactions within the core framework of geochemical cycles, offering a novel abiotic pathway explanation for understanding the global ‘missing carbon sink’ and formation of inert organic matter reservoirs, but also establishes a robust theoretical foundation for developing green, low-carbon technologies such as mineral-regulated soil carbon sequestration, sludge resource recovery, and marine carbon sequestration. Future research should quantify the absolute flux of this pathway within real environmental matrices and investigate the synergistic and competitive effects of different mineral types and microbial communities on interfacial processes.

# Pore-scale spatial heterogeneity of moisture and microbe interactions during moisture evaporation

**ABSTRACT**

Soil aggregates are fundamental structural units that regulate microbial habitats and the fate of soil organic carbon. The spatial heterogeneity of water and oxygen at the pore scale within aggregates directly influences microbial metabolic activities, thereby determining whether organic carbon is rapidly decomposed or stabilized over the long term. However, due to the high heterogeneity and complexity of soil structure, these microscale processes have long been challenging to quantify and resolve directly. Here, we combined millimeter-scale microfluidic chips simulating soil aggregate pore networks, confocal laser scanning microscopy, and time-of-flight secondary ion mass spectrometry to simultaneously visualize pore water distribution, microbial biomass, extracellular polymeric substances (EPS), and key molecular features of microbial metabolism. Our results show that under conditions of water evaporation, radial water gradients and spatial differentiation of microbial survival gradually form within aggregates. Due to higher oxygen accessibility in the outer pores, microbial activity is elevated, leading to increased microbial biomass and EPS secretion in the outer layer, which enhances water retention and slows water loss during evaporation. In contrast, internal pores experience oxygen limitation, suppressing microbial growth; during evaporation, internal regions lose water preferentially, and microbes transition from oxygen limitation to water stress, maintaining low metabolic activity over time. At the molecular level, these spatial differentiations are further explained by biological mechanisms. Microbial communities in the outer pores exhibit growth-oriented resource allocation, characterized by enhanced protein and phospholipid signals and EPS enriched in protein components, indicative of high metabolic activity and rapid organic matter turnover. In contrast, microbes in the internal pores allocate more resources toward defense and environmental maintenance, as shown by EPS rich in polysaccharides, reduced metabolic activity, and localized accumulation of microbial residues. The coexistence of these different survival strategies within aggregates reveals, at the molecular scale, how pore-scale water and oxygen gradients drive functional partitioning of microbial communities. Overall, this study reveals the pore-scale interactions between water and microbes and their effects on spatial heterogeneity in organic carbon turnover. These findings provide mechanistic insights into aggregate-scale carbon stabilization and turnover and offer theoretical and technical support for understanding the dynamic regulation of soil water and carbon fluxes under changing climatic conditions.

**ABSTRACT**

Despite the critical role rhizosphere microbiomes play in plant growth, manipulating microbial communities for improved plant productivity remains challenging. One reason for this is the lack of knowledge on how complex substrates secreted in the microbiome ultimately shape the microbe-microbe and plant-microbe interaction in relation to plant growth. One such complex substrate is poly-γ-glutamic acid, which is a microbially derived extracellular polymer. While it has previously been linked with plant growth-promotion, the underlying mechanisms are not well understood. Here we show that this compound benefits plants by fostering cross-feeding networks between rhizosphere bacteria. We first experimentally demonstrate that poly-γ-glutamic acid application increases potassium bioavailability for tomato plants by driving a shift in the rhizosphere bacterial community composition. Specifically, application of poly-γ-glutamic acid increased the relative abundance of *Pseudomonas nitroreducens* L16 and *P. monteilii* L20 bacteria which both promoted tomato potassium assimilation by secreting potassium-solubilizing pyruvic acid and potassium-chelating siderophores, respectively. Although either *Pseudomonas* strain could not metabolize poly-γ-glutamic acid directly, the application of poly-γ-glutamic acid promoted the growth of *Bacillus* species, which in turn produced metabolites that could promote the growth of both *P. nitroreducens* L16 and *P. monteilii* L20. Moreover, the *P. monteilii* L20 produced 3-hydroxycapric acid, which could promote the growth of *P. nitroreducens* L16, resulting in commensal cross-feeding interaction between plant growth-promoting bacteria. Together, these results show that poly-γ-glutamic acid plays a crucial role in driving plant growth-promotion via bacterial cross-feeding networks, highlighting the opportunity for using microbially derived, complex substrates as catalysts to increase agricultural productivity.

## ABSTRACT

Root–microbe interactions strongly influence the production of microbial extracellular polymeric substances (EPS), a key intermediate linking microbial metabolism to soil organic carbon (SOC) stabilization. However, how nitrogen (N) deposition regulates EPS production in soils with and without root influence remains unclear. Here, we applied long-term N addition (0, 40, 80 kg $N \cdot ha^{-1} \cdot yr^{-1}$) combined with root exclusion in a subtropical *Castanopsis carlesii* natural forest to assessed how N enrichment and roots presence jointly affect microbial EPS production, production efficiency, and contribution to SOC. Nitrogen addition showed a nonlinear response, reducing EPS concentrations by 20–26%, mainly through declines in microbial biomass carbon (MBC) and carbon use efficiency (CUE), which together constrained carbon available for extracellular synthesis. In contrast, EPS production efficiency increased by up to 40%, and was accompanied by elevated carbon- and phosphorus-acquiring enzyme activities, indicating enhanced metabolic allocation under nutrient imbalance. Although EPS-derived carbon (EPS-C) accounted for only 0.3%–0.5% of SOC, its proportion increased significantly under nitrogen addition, particularly in root-free soils. This finding suggests that EPS may serve as an important microbial carbon pool under conditions of limited plant input or weakened root activity. These results demonstrate that long-term N deposition reorganizes microbial carbon allocation and extracellular stabilization pathways through coordinated shifts in MBC, CUE, and enzyme stoichiometry in subtropical forest soils.

## ABSTRACT

Cropland abandonment is an important ecological restoration practice on the Loess Plateau, enhancing soil quality and regional carbon (C) sequestration. Microbial metabolic residues, including microbial necromass (MNC) and extracellular polymeric substances (EPS), represent major contributors to soil organic carbon (SOC) pools. However, how climate change regulates microbial residue accumulation and its contribution to SOC in abandoned cropland remains unclear. Here, we investigated a 12-year abandoned cropland ecosystem in the loess hilly region using an in situ climate-manipulation experiment that simulated warming (~1.42 °C) and five precipitation gradients. Biomarker-based microbial residue analysis and microbiome approaches were combined to clarify the responses and underlying mechanisms. (1) Increased precipitation, rather than warming, significantly enhanced topsoil SOC pools and their relative proportions, with SOC increasing by an average of 1.91% for every 10% increase in precipitation. Warming mainly increased microbial biomass C but had no significant effect on SOC pools, and its interaction with precipitation showed antagonistic effects. Mineral-associated organic matter (MAOM) contained approximately twice as much carbon as particulate organic matter (POM) (3.84 vs. 1.95 g $kg^{-1}$) and exhibited greater chemical recalcitrance. However, increasing precipitation reduced MAOM recalcitrance, likely due to enhanced fresh C inputs and weakened mineral protection under higher soil moisture. (2) Both MNC and EPS contents increased with rising precipitation gradients, while warming promoted only the accumulation of EPS uronic acids. Fungal necromass dominated MNC, with contents approximately six times higher than bacterial necromass. EPS was mainly composed of polysaccharides (63.12%), followed by proteins (26.59%) and glyoxylates (10.29%). The accumulation coefficients of MNC and EPS were 13.93 and 2.12, contributing 31.45% and 4.75% to SOC, respectively. Although MNC showed a much higher accumulation coefficient and C contribution than EPS, increasing precipitation significantly reduced the relative contribution of MNC while enhancing that of EPS, indicating that improved moisture conditions favor EPS-mediated C sequestration. SOC fractions and microbial residue contents increased over time following abandonment, highlighting the positive effects of restoration on soil C accumulation. (3) Microbial community responses showed that warming reduced bacterial diversity and network complexity, whereas increasing precipitation enhanced both, with warming offsetting precipitation-driven gains. Increased precipitation alleviated microbial nitrogen limitation and competitive pressure, and promoted biomass production (Y-strategy) and resource acquisition (A-strategy), while reducing stress-tolerance (S-strategy). Microbial community assembly processes were strongly linked to diversity patterns, indicating climate-driven shifts in microbial assembly mechanisms. (4) Driving mechanisms differed markedly between MNC and EPS. While both were positively correlated with plant biomass, soil moisture, substrate availability, and mineral protection, microbial community properties explained only a small fraction of MNC variation (≤3%), but accounted for most of the EPS variation (>50%). Structural equation modeling revealed that MNC accumulation was primarily driven by substrate availability, whereas EPS accumulation was jointly regulated by soil environment, substrate supply, mineral protection, and microbial traits. Notably, EPS enhanced both POM- and MAOM-C, resulting in a stronger direct effect on SOC than MNC.Overall, this study highlights precipitation as a dominant regulator of microbial residue-derived carbon sequestration in abandoned cropland on the Loess Plateau and provides mechanistic insights for predicting regional carbon sinks under future climate scenarios.

## ABSTRACT

Microbial cell and extracellular polymeric substances (EPSs) are recognized as critical precursors of soil organic carbon (SOC), yet their differential stabilization mechanisms remain poorly understood. To elucidate the micro-mechanisms governing the transformation of these "microbial legacy" into SOM, we conducted a 112-day incubation experiment using soil amended with $^{13}$C-labeled bacterial and fungal biomass components (intact cells, extracellular polysaccharides[EPSc], and extracellular proteins [EPSp]) . We tracked C partitioning into $CO_2$, diverse SOM fractions (physical and chemical), and the change of microbial necromass carbon (MNC) to compare their stabilization pathways.

Results indicated that substrate origin and chemical composition distinctively regulated carbon fate. Fungal-derived components exhibited superior persistence with >81% SOC recovery, while bacterial EPSp showed the highest mineralization (21.3%). Notably, bacterial components induced persistent negative priming effects, effectively suppressing native SOC decomposition, whereas fungal EPSp triggered positive priming despite low self-mineralization. EPSc preferentially stabilized through mineral association (MAOC), with F-EPSc uniquely achieving sustained MAOC accumulation. EPSp predominantly contributed to humic acid formation, particularly F-EPSp (39% recovery in HA-C). Cell components promoted MNC accumulation, while EPSc addition dramatically depleted bacterial necromass, shifting communities toward fungal dominance. Microbial community analysis identified *Bacillus* (bacteria) as the primary driver of rapid mineralization, while *Mortierella* (fungi) was crucial for carbon assimilation and stabilization. Partial least squares path modeling (PLS−PM) demonstrated thatfungal diversity was the strongest positive driver of SOC accumulation (r=0.836) through mineralization suppression, while bacterial diversity accelerated carbon loss.

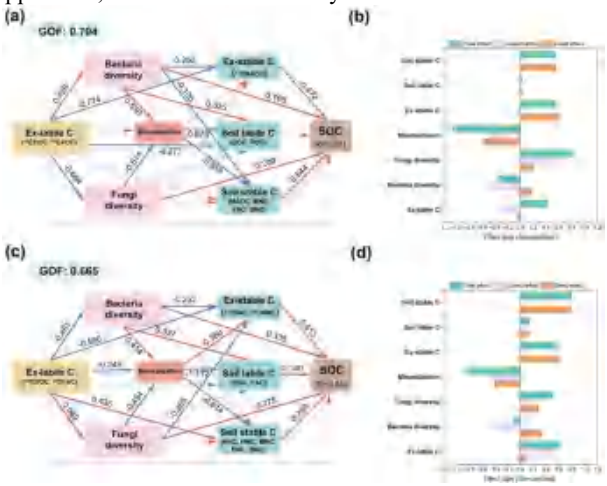

**Figure 1.** PLS−PM analysis of the effects of DOC, bacterial and fungal microbial communities, mineralization, MAOC, POC, FA-C, HA-C, HM-C, and microbial necromass carbon (MNC, FNC, BNC) on SOC. The models are based on two different soil organic matter fractionation schemes: (a, b) physical density fractionation and (c, d) chemical humus fractionation.

These findings demonstrate that fungal cells and EPSc serve as superior precursors for stable SOM, while bacterial proteins favour rapid turnover. This study provides process-level evidence for the SOM transformation, demonstrating that microbial biomass components undergo different transformation pathways, linking biomass chemistry to distinct SOM formation pathways within both continuum and humus frameworks, and highlighting the trade-off between bacterial-driven mineralization and fungal-mediated SOC sequestration.

## ABSTRACT

Humic acid (HA) as a soil organic matter (NOM) can participate in the interaction between proteins and clay minerals, depending on clay type, HA and protein content, and solution conditions. The effect of HA on the interaction of lysozyme (LSZ) with kaolinite (Kao) and montmorillonite (Mont) was investigated at (initial) $pH_i$ 5 and 8. LSZ adsorption on clays in the presence of HA is dominated by adsorption of HA/LSZ complexes. The HA/LSZ mass ratio ($f_{IEP,pH}$) at the iso-electric point (IEP) is pH dependent. At $f < f_{IEP,pH}$ the HA/LSZ complexes are positively charged and adsorb well to the negatively charged Mont and Kao surface fractions. The adsorption levels on Mont are considerably larger than on Kao, which is mainly due to the much larger area fraction of modestly hydrophobic basal plates of Mont. The presence of HA increased the plateau adsorption of LSZ on Kao and Mont for both $pH_i$ values, and the LSZ adsorption increased with increasing HA content and $pH_i$ values. At $pH_i$ 8 complications arised for low initial LSZ concentrations, for $f < f_{IEP,pH}$ the HA/LSZ complexes were only weakly positive and formed dispersed aggregates and for $f > f_{IEP,pH}$ the HA/LSZ complexes were negative, both conditions caused relatively high equilibrium concentrations of LSZ in solution that decreased with increasing initial LSZ concentration. The present results enhance our insight in protein soil interactions for the case that clay particles are brought in contact with aqueous solutions that contain modest amounts of both NOM and protein and stress the importance of the NOM/protein mass ratio and solution pH.

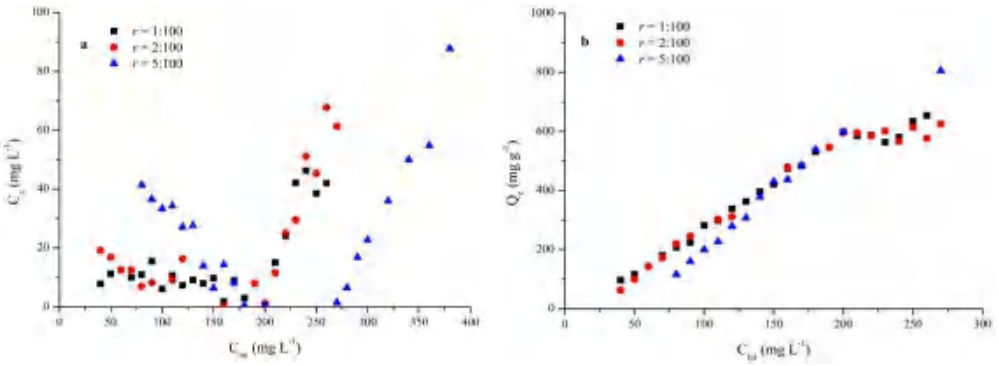

Figure 1. LSZ adsorption on montmorillonite at at $pH_i$ 8 with different HA/clay mass ratios *r*.

**ABSTRACT**

Intensive agriculture degrades soil health, while the recovery of abandoned soils may take decades. Sustainable soil management requires strategies that improve soil physicochemical conditions while supporting soil biological functioning. In this sense, biochar, produced through the pyrolysis of organic waste, has emerged as a promising amendment to improve soil physicochemical properties and stimulate soil biological processes, although its effects depend strongly on soil characteristics and management history.

In this study, three contrasting agricultural soils from southern Spain (olive grove, avocado plantation and abandoned cereal field) were amended with biochar (produced by *FENIX* project; pyrolyzed at 500 °C for 15 min) at rates of 2.5% and 5% (v/v) and incubated for three months alongside untreated controls. Soil physicochemical and biological properties (CEC, pH, nutrients, enzymatic activities, microbial biomass, respiration, and fungal and prokaryotic rhizospheric community composition) were evaluated, and a greenhouse pot experiment with lettuce (three consecutive one-month cultivation cycles) was conducted to assess plant responses.

Results pointed out that soil type and management history were the primary drivers of variability among samples. When analysed individually, biochar amendments induced substantial changes in several soil properties after the incubation period. In the olive and abandoned cereal soils, biochar application increased the availability of exchangeable $K^+$, likely reflecting the high K content of the biochar. In contrast, soluble $Mg^{2+}$ and $Ca^{2+}$ decreased in the avocado soil, possibly due to adsorption processes. In the abandoned cereal soil, urease activity increased with biochar addition, suggesting enhanced microbial activity linked to increased carbon inputs. Biochar amendments also reduced the solubility or availability of several micronutrients (Zn, Cu, B) and decreased bioavailable Mn and available P. Increasing biochar application rates drove measurable shifts in microbial community composition and interconnectivity, indicative of altered nutrient cycling and carbon dynamics. Despite these changes in soil properties and biological activity, no significant effects on lettuce growth were observed, possibly due to the short experimental duration, the rapid crop cycle, and the absence of strong nutrient limitations.

These results highlight the strong soil-specific responses of biochar amendments and underscore the importance of considering soil type when evaluating biochar as a strategy to enhance soil health and biological functioning in Mediterranean agroecosystems.

**ABSTRACT**

Soil biota drive many essential soil functions that underpin ecosystem services in agriculture. Assessing soil biodiversity is therefore crucial for understanding the effects of management practices, such as tillage, on biological soil health. Molecular techniques including DNA metabarcoding are widely used to study soil biodiversity and have proven effective for microbial soil organisms. To extend their potential to soil fauna, methodological adaptations are needed, particularly to accommodate the larger body sizes and different environmental DNA (eDNA) distribution patterns associated with faunal organisms. In this study we analyzed extracellular eDNA (exDNA) extracted from larger volumes of soil to enable the simultaneous assessment of multiple soil microbial and faunal taxa. Employing an integrated metagenomic and metabarcoding approach, we applied this exDNA method to assess the functional diversity of belowground communities in arable soils of Austria subjected to different tillage intensities. Faunal taxa were assigned to functional categories based on traits linked to their trophic roles and ecological strategies, which could be used to derive bioindicators for assessing soil health. Similarly, microbial analysis targeted key functional groups, and genes associated with vital soil functions. Such comprehensive assessments of soil functional diversity using exDNA may advance integrative soil health diagnostics to thoroughly evaluate the impacts of agricultural management practices.

# Long-Term Effects of Nitrogen and Lime Application on Plant–Microbial Interactions and Soil Carbon Stability in a Semi-Arid Grassland

**Kwenama Buthelezi[1*], Nkosinomusa Nomfundo Buthelezi-Dube[1]**

*[1] School of Agricultural, Earth and Environmental Sciences, University of KwaZulu-Natal, P. Bag X01, Scottsville, Pietermaritzburg 3201, South Africa;*

** kwenamahbuthelezi@gmail.com*

**ABSTRACT**

This study investigated the long-term (70 years) effects of N fertilisation (ammonium nitrate [AN], ammonium sulphate [AS]) at 70 and 211 kg N kg/ha, and liming (L) on plant–microbial interaction and soil carbon stability in a semi-arid grassland in South Africa. Aboveground biomass increased with N addition, particularly AN211, showing a 119% increase compared to the control, while both liming and N applications increased belowground biomass. Nitrogen addition significantly altered plant stoichiometric ratios, with root N ratios showing greater treatment-induced variation (12.7–51.3) than shoot N ratios (10.2–16.8). Microbial biomass carbon peaked with AN70 treatment, while dehydrogenase activity was highest in lime-only plots but suppressed in non-limed N treatments. Conversely, urease activity was highest in the control group and suppressed in most fertilised treatments. Despite increased biomass production, SOC remained unchanged across treatments (49.7–57.6 g/kg), whereas soil pH was lowest (<3.5) and highest (>6) under N fertilisation and lime, respectively. PCA revealed distinct clustering of treatments, with N forms differentially affecting plant allocation patterns and microbial parameters. This study demonstrates that plant–soil–microbe stoichiometric imbalances and pH-induced limitations on microbial function explain the disconnect between plant productivity and carbon sequestration in this semi-arid grassland ecosystem.

# Linking Soil Food Web Stoichiometry to Ecosystem Function and Soil Health

**Qi Li[1*], Yang Bai[1], Yingbin Li[1], Xiaofang Du[1], Wenju Liang[1]**

*Institute of Applied Ecology Chinese Academy of Sciences, Shenyang, China*

*liq@iae.ac.cn

**ABSTRACT**

Ecological stoichiometry serves as a fundamental mechanism governing nutrient cycling in ecosystems. Organic substitution changes soil carbon, nitrogen, and phosphorus balance by introducing exogenous organic materials with distinct stoichiometric profiles, thereby compelling soil biota to adapt through multifaceted strategies. However, systematic understanding of how the soil food web responds to such stoichiometric imbalance remains elusive. To address this knowledge gap, we examined the response of soil food web community composition and multi-trophic network structure to elemental stoichiometric shifts in agricultural ecosystems. Organic substitution consistently increased the relative abundance of K-strategist bacteria, consumer protists, and bacterivorous nematodes, while reducing parasitic protists and plant-parasitic nematodes. Arthropod communities, particularly *Mesostigmata* and *Cryptostigmata* mites, exhibited pronounced responses. These shifts were strongly correlated with soil nutrient limitation and stoichiometric imbalances. Furthermore, organic substitution reconfigured the elemental stoichiometric network of the "crop-soil-biota" continuum by modulating nutrient availability and biological processes. Our findings elucidate the mechanisms underlying multi-trophic reorganization within soil food webs and demonstrate how stoichiometric coupling mediates ecosystem responses to resource inputs. This work advances ecological stoichiometry theory in soil ecology and provides a theoretical framework for optimizing agricultural nutrient cycling through the lens of "resource input–biological response–functional output" dynamics.

## ABSTRACT

Enzyme activities serve as critical indicators of soil biological function and nutrient cycling, yet their temporal dynamics and spatial distribution following cover crop incorporation are not well understood in degraded sandy soils. This study investigated how monoculture versus mixed cover cropping systems influence the temporal and depth-dependent patterns of key hydrolytic enzymes mediating carbon, nitrogen (N), and phosphorus (P) cycling in Myakka sandy soils of subtropical Florida. Six treatments were established at the Gulf Coast Research and Education Center, Wimauma, FL in May 2024: sorghum-sudangrass (SS) 33.63 kg ha$^{-1}$, sunn hemp (SH) 56.04 kg ha$^{-1}$, southern pea (SP) 56.04 kg ha$^{-1}$, SH + SP (28.02 + 28.02 kg ha$^{-1}$), SH + SS (28.02 + 16.81 kg ha$^{-1}$), and weedy fallow (WF) control using a randomized complete block design with three replications. Baseline conditions revealed characteristic limitations of degraded sandy soils: low soil organic matter (1.66% surface, 1.14% subsurface), acidic pH (5.27 surface), and stratified P availability (311.5→181.5 mg kg$^{-1}$ with depth). Following 80-day growth periods, cover crop biomass was incorporated and soil enzyme activities (β-glucosidase, N-acetyl-β-D-glucosaminidase, and acid phosphatase) were quantified colorimetrically at 0–15 and 15–30 cm soil depths across 2, 4, and 6 weeks post-incorporation. Mixed-model analysis of variance (ANOVA) revealed pronounced temporal dynamics ($p<0.001$), depth stratification (P<0.001), and enzyme-specific responses (P<0.001), with significant treatment × enzyme ($p<0.001$) and treatment × week× enzyme ($p=0.005$) interactions. All enzymes exhibited synchronized peak activities at week 4 post-incorporation, and declined thereafter, while surface horizons maintained 50–100% greater activities than subsurface layers. Although main treatment effects were statistically non-significant ($p=0.199$), the SH+SS legume-grass mixture consistently demonstrated superior enzyme activities, particularly for acid phosphatase and N-acetyl-β-D-glucosaminidase, suggesting enhanced microbial processing of organic P and N substrates. These results showed a critical 4-week temporal window post-incorporation where enzyme-mediated nutrient release is maximized, providing actionable guidance for optimizing subsequent crop planting schedules to synchronize nutrient availability with crop demand while minimizing leaching losses in vulnerable sandy soils. The superiority of legume-grass mixtures indicates that functional diversity in cover crop systems enhances enzyme-mediated biogeochemical cycling, offering an innovative approach to improving nutrient retention in chemically and biologically degraded subtropical agroecosystems.

# Steering soil microbiomes for healthier crops

**T. Martijn Bezemer**[1*]

[1] *Institute of Biology, Leiden University, Leiden, The Netherlands*

*t.m.bezemer@biology.leidenuniv.nl

**ABSTRACT**

A healthy soil microbiome is important for plant growth. This is certainly true in agricultural systems, and is now acknowledged broadly. I will present results from our recent work showing how the composition and diversity of soil microbial communities influence the growth and, more importantly, also the health and nutritional quality of crops. An important question is how to change these soil microbial communities to improve crop growth and health. I will discuss the transient nature of soil microbiomes and how we can use plants to steer the composition of soil microbiomes. I will show how specific the effects are of plants on the soil microbiome, but also how sensitive plants are to changes in the soil microbiome. I will also show how neighboring plants influence the root associated microbiome of a focal crop and the consequences of the neighbor effects on the microbial community for plant growth and yield. By understanding how different crops influence desired groups of soil microorganisms and the temporal dynamics of these effects we can design combinations of crops, in rotation or intercropping systems that improve the performance of a focal crop.

# Rewiring Micro-Food Webs: How Copper Nanopesticides Can Reshape Nitrogen Fluxes via Trophic Decoupling

**ABSTRACT**

The extensive application of copper-based nanopesticides (Cu-based NPs) in agroecosystems can pose significant ecological risks to soil nitrogen (N) cycling through microbial-mediated mechanisms, yet food web-driven regulatory feedbacks remain poorly understood. Through a microcosm experiment with CuO nanoparticles (CuO NPs) and silica-encapsulated CuO@$SiO_2$ NPs (applied at 20 and 200 mg/kg), we demonstrate how micro-food web interactions (bacteria, fungi, protists, nematodes) govern N transformation dynamics. Integrated enzymatic and ecological network analyses revealed that both NPs reduced microbial biomass nitrogen (MBN) and bioavailable N species. Critically, high-dose CuO@$SiO_2$ (200 mg/kg) strongly inhibited nitrite reductase (NiR, 44.8%), creating a denitrification bottleneck. Elevated β-1,4-glucosidase: β-1,4-N-acetyl-glucosaminidase (BG: NAG) ratios indicated decoupled carbon-nitrogen cycling, favoring oligotrophic bacteria (e.g., *Sphingomonas*) over sensitive fungi (*Olpidiomycota*). NPs disproportionately impacted high-trophic-level microfauna, restructuring micro-food web topology. Network modeling uncovered concentration-specific trophic cascades: CuO@$SiO_2$ intensified protistan predation, disrupting nematode-microbe linkages and weakening top-down control of nitrifiers/denitrifiers. This triggered 71.8% higher $N_2O$ emissions while reducing soil N supply capacity by 36.1% at high-dose NP exposure. Conversely, low-dose CuO NPs maintained N turnover through reinforced bacterial-protist-fungal connectivity. Crucially, NP impacts exhibited non-linear, threshold-mediated dynamics: low concentrations induced metabolic adaptations (enzymatic stoichiometry shifts), while high doses caused functional collapse (denitrification inhibition). Our findings establish that micro-food web restructuring—not merely microbial toxicity—determines NP effects on biogeochemical cycles. This underscores the imperative to incorporate trophic interactions into nanomaterial risk assessments for accurate prediction of agroecosystem functions.

# Contrasting global patterns and drivers of soil bacterial and fungal diversity responses to crop rotation

**Chong Li[1*], Kecheng Wang[1], Boran Liu[1], Jiaojiao Liao[1], Zhengfeng An[1], Scott X. Chang[1*]**

[1] *Department of Renewable Resources, University of Alberta, Edmonton, Alberta, Canada*

*Chong Li (chong13@ualberta.ca); Scott X. Chang (sxchang@ualberta.ca)

**ABSTRACT**

Crop rotation is widely implemented to enhance agricultural sustainability, with its benefits for soil health and crop productivity closely linked to changes in the soil microbiome. However, the global-scale effects of crop rotation on soil microbial communities remain poorly understood. Here, we conducted a global meta-analysis combining 2177 paired observations, based solely on high-throughput sequencing data, to evaluate how crop rotation influences bacterial and fungal diversity, community structure, and their relationships with crop yield and environmental factors. We found that crop rotation significantly increased bacterial alpha diversities (Shannon diversity and species richness) but not beta diversity. In contrast, crop rotation significantly increased fungal beta diversity but not alpha diversity. Crop rotation altered both bacterial and fungal community structure. Moreover, transitioning from legume to non-legume crops in crop rotations induces greater changes in bacterial Shannon diversity and fungal beta diversity, as well as in both bacterial and fungal community structure, than the reverse transition. Bacterial Shannon and fungal beta diversities increase with rotation duration and the number of rotational cycles. Random forest models revealed that microbial responses to crop rotation are modulated by mean annual temperature, but not by soil physicochemical properties. Moreover, soil texture influenced the response ratio of fungal richness, with significant decreases in fine-textured soils. The response ratios of bacterial and fungal alpha diversity were positively correlated with the response ratios of crop yield and soil chemical properties (e.g., pH, soil organic carbon, available nutrients), while the response ratios of beta diversity and community structure were not. Our findings demonstrate that bacterial and fungal communities respond differently to crop rotation, and that increases in microbial alpha diversity under rotation mediate improvements in soil health and crop productivity. Future research should focus on microbial functional responses and crop type transitions under diverse agroecosystems to better integrate soil microbiomes into sustainable agricultural systems and maximize the benefits of crop rotation.

# The effect of iron-bound organic carbon on fungal denitrification in regulating upland red soils $N_2O$ emission

**Huifang Xu[1*], Teng Yu[1], Siyi Li[1], Chenyi Lao[1] and Wenzhao Zhang[2]**

[1] *Jiangxi Agricultural University (Research Center on Ecological Sciences, Nanchang, China)*

[2] *Institute of Subtropical Agriculture (Chinese Academy of Sciences, Changsha, China)*

*xhuifang@yeah.net

**ABSTRACT**

Agricultural soil serves as a significant source of anthropogenic $N_2O$ emissions. Compared to bacteria, the role of fungi in $N_2O$ emissions from upland soil cannot be ignored. Our previous research has shown that fungi contributed approximately 60.11% of $N_2O$ emissions in acidic red soil of upland. Notably, acidic red soil is characterized by a high content of iron elements, which readily combine with soil organic carbon to form iron-bound organic carbon (Fe-OC). Besides, our study showed that a positive correlation between Fe-OC and fungal denitrification potential. However, the mechanism by which iron-bound organic carbon affects fungal denitrification on $N_2O$ emission in upland red soil is still unclear, especially under the addition of exogenous organic matter. Our study aims to investigate dynamic changes in iron oxide forms, their concentrations, and associated organic carbon (Fe-OC) in upland acidic red soil with long-term addition of exogenous organic matter through field in situ experiments. Furthermore, our examined the impact of $^{15}N$-labeled Fe-OC on soil $N_2O$ emissions-based laboratory cultivation experiments. Our findings of this research can provide an important theoretical basis for the mechanism of denitrifying fungi affected by iron-bound organic carbon in aridic red soil impacting agricultural $N_2O$ emissions.

# Unraveling soil microbial guilds driving phosphorus, nitrogen, and carbon transformations through multi-omics approaches

**Felipe Bastida[1*], Celia García-Díaz[1], Belén Barquero[1], José Luis Moreno[1], and Rubén López-Mondéjar[1]**

*[1] CEBAS-CSIC, Department of Soil and Water Conservation, Murcia, Spain*

*fbastida@cebas.csic.es

**ABSTRACT**

Our studies provide new insights into the ecological and functional complexity of soil microbial communities and their central role in regulating the biogeochemical cycles of phosphorus (P), nitrogen (N), and carbon (C) in agricultural and semi-natural soils. Using an integrative multi-omics framework—including metagenomics, metaproteomics, metatranscriptomics, and metagenome-assembled genomes (MAGs)—we characterized the taxonomic composition, functional specialization, and environmental responses of soil microbiomes under varying fertilization practices, crop phenology, and organic matter dynamics. We identified highly specialized microbial guilds that drive key transformations within the P, N, and C cycles. In the P cycle, a functional division was observed between microorganisms responsible for the solubilization of inorganic P and those involved in the mineralization of organic P. Actinobacteria were predominant carriers of solubilization genes, while other bacterial and archaeal groups specialized in organic P mineralization, revealing evolutionary adaptations to distinct nutrient sources. Archaea, historically underestimated in P cycling, were found to encode multiple P-metabolism genes, indicating complementary or even essential roles alongside bacteria. Metaproteomic data highlighted the alkaline phosphatase PhoX as a potential biomarker of P bioavailability. In the nitrogen cycle, our results demonstrate that microbial functional niches are sharply defined and largely governed by crop phenology, which modulates the abundance and activity of nitrification and denitrification genes more strongly than fertilization. Distinct guilds of nitrifiers (e.g., Nitrososphaeraceae) and denitrifiers (e.g., Propionibacteriaceae) were identified, each with discrete metabolic roles. These findings indicate that synchronizing fertilization schedules with phenological stages of high microbial activity can improve nutrient use efficiency and mitigate environmental losses. Regarding the carbon cycle, our analyses challenge the traditional paradigm that fungi dominate the decomposition of complex organic matter. We identified diverse bacterial decomposer guilds—including Chitinophaga, Pedobacter, Terriglobus, and Asticcacaulis—specialized in degrading chitin, β-1,3-glucans, and cellulose. Metatranscriptomic evidence showed that bacterial decomposers often exhibited higher metabolic activity than fungi, underscoring their crucial role in organic matter turnover and carbon sequestration. Together, these findings highlight the strong influence of plant phenology on microbial functionality and reveal the need to align nutrient management with the dynamic activity of soil microorganisms. The integration of multi-omics data also enabled the identification of functional biomarkers with potential for predictive applications in soil health assessment. By coupling molecular data with machine learning, we provide a framework to anticipate soil microbiome responses to management or climatic change. Overall, this research advances the mechanistic understanding of soil microbial ecology and supports the development of microbiome-informed strategies for sustainable nutrient management, soil fertility enhancement, and climate-smart agriculture.

# Multi-scale Biochar-hydrogel for Enhanced Soil Health and Crop Production

**Xiaoping Xin[1*], Haseeba Maryam[1]**

[1] *School of Natural Resources, Division of Plant Science and Technology, University of Missouri*

*Columbia, MO 65211, USA*

xinx@missouri.edu

**ABSTRACT**

Soil degradation, nutrient loss, and declining water-use efficiency are major challenges threatening agricultural productivity and sustainability under changing climate conditions. Conventional fertilizers and soil amendments often fail to maintain nutrient availability and microbial viability over time, leading to inefficient nutrient use and increased environmental losses. Biochar (BC) and hydrogels (HG) have individually shown promise for improving soil fertility and water retention; however, their performance remains inconsistent due to differences in material properties, soil types, and management conditions. This research develops and tests innovative soil amendments made from multi-scale biochar–hydrogel (BC–HG) nanocomposites that incorporate nano-biochar (NBC) to improve soil health and crop productivity. These materials are designed to enhance soil structure, regulate water retention and release, increase nutrient sorption, and support beneficial soil microbes under stress conditions such as drought or nutrient limitation. Despite their potential, the optimal material composition and mechanisms by which these composites affect soil processes and plant–microbe interactions are not well understood, and field-scale evidence remains limited. To address these gaps, the research integrates materials engineering, soil biogeochemistry, and plant-microbe ecology to (1) develop and characterize BC–HG nanocomposites for improved microbial encapsulation and delivery, (2) evaluate their effects on nutrient cycling, microbial activity, and plant growth under controlled drought and reduced fertilizer inputs, and (3) validate their performance and environmental impacts in contrasting field soils. The outcomes will provide new insights into how nanocomposite design influences soil function and crop productivity, advancing practical, sustainable technologies for enhancing nutrient-use efficiency, soil resilience, and agricultural sustainability under changing climate conditions.

* linda.lindongi@research.uwa.edu.au

**ABSTRACT**

Improving sandy soil structure and fertility requires a combined approach integrating organic and mineral amendments under plant influence. This study investigated the impact of compost, clay, and their combination, with or without plant presence, on the distribution of soil fractions and biochemical properties. A glasshouse experiment was conducted using Kikuyu grass (*Pennisetum clandestinum*) grown in sandy soil amended with compost (2–4% w/w), bentonite clay (2% w/w), or their combinations. After 12 weeks, soils were fractionated into macro (>2 mm), meso (0.25–2 mm), and micro (<0.25 mm) fractions, and analysed for microbial biomass carbon (MBC), pH, EC, $NH_4^+$, $NO_3^-$, and cation exchange capacity (CEC). A significant interaction between treatment and plant presence occurred for macro- and meso-fractions, indicating that plant roots modified the effects of amendments on structural dynamics. Compost, alone or combined with clay, promoted macro-fraction formation and enhanced MBC, whereas clay primarily contributed to improvements in pH and CEC. The presence of plants amplified MBC and $NH_4^+$ but decreased $NO_3^-$ and EC, suggesting enhanced microbial activity and nutrient uptake within the rhizosphere. Overall, compost acted as the main driver of structural and biological improvement, while clay provided chemical buffering and stabilization. The combined application maintained structure under plant influence, highlighting the complementary roles of organic–mineral interactions in improving sandy soil function.

**ABSTRACT**

Sandy soils are inherently low in physical, chemical, and biological fertility, limiting their capacity to retain nutrients and organic matter. A glasshouse experiment was conducted to examine the effects of kaolinite clay (0 and 5%), hay residue as an organic amendment (0 and 4%), and nitrogen–phosphorus–sulphur (NPS) fertilizer on the physical and biological properties of a sandy soil. Soils were sampled after 2, 12, and 20 weeks to assess changes in soil fraction distribution (micro <0.25 mm, meso 0.25–2.0 mm, and macro >2.0 mm), microbial biomass, nutrients, and microbial community structure. A two-way ANOVA revealed that harvest time, treatment, and their interaction significantly affected all measured parameters. Treatments combining clay with hay residue, with or without fertilizer, significantly increased macro-fraction formation by approximately 2–4 times compared to the control ($p < 0.001$), indicating improved soil structure and aggregate stabilization over time. Microbial biomass carbon and nitrogen were also higher in these treatments ($p < 0.05$), whereas fertilizer alone or with clay had limited effects. Fungi were more prominent during the intermediate decomposition stages (12 weeks), particularly in the larger fractions, while bacteria dominated the later phases. Organic amendments, especially when combined with clay and fertilizer, enhanced microbial diversity and functional gene abundance related to carbon degradation (endoglucanase) and nutrient cycling (ureC). Overall, the co-application of clay and hay residue improved soil structure, microbial activity, and nutrient retention, demonstrating synergistic benefits for restoring sandy soil fertility.

# Impacts of sample storage conditions on extracellular DNA-based assessments of soil biodiversity

**Philippe R. Belliard [1*], Nadine Praeg [2], Oskar Rennstam Rubbmark [1] and Michael Traugott [1]**

[1] *Zoology Department, Universität Innsbruck, Innsbruck, Austria*

[2] *Microbiology Department, Universität Innsbruck, Innsbruck, Austria*

*philippe.belliard@uibk.ac.at

**ABSTRACT**

The study of soil biodiversity is crucial to understand the effects of management practices on soil functions that are essential for the delivery of ecosystem services. Innovative methods of extracellular soil environmental DNA (exDNA) extraction using a phosphate buffer method provide a promising approach to study the near totality of soil organisms from large volumes of soil. However, despite its application in numerous soil biodiversity studies, little research has been done with regards to procedural aspects of this method, such as the importance of sample storage conditions. While storage at elevated temperatures can promote exDNA degradation and induce shifts in microbial communities that deviate from conditions in the studied environment, freezing soil samples leads to cell lysis and the subsequent release of intracellular DNA into the extracellular milieu, which may be undesirable. Furthermore, it is unknown to what extent changes in the exDNA fraction occur over time during storage and how they may affect estimates of soil community structure and diversity. This study investigated such potential effects of sample storage time and temperature on soil exDNA analyses. Aliquots of a composite soil sample from an arable field were stored at room temperature (~20°C), 4°C or -20°C for a duration of 1, 3, 7, or 14 days. We evaluated the effects of the different treatments on the quantity of phosphate buffer-extractable exDNA, as well as on biodiversity metrics of microbial and faunal communities derived from exDNA metabarcoding analyses. The results of this experiment will contribute to optimizing exDNA-based protocols for multi-taxa biodiversity surveys and research on best practices in sustainable soil management.

# A data-driven methodology to identify key biological indicators linked with ecosystem services in agricultural soils

**Alberto Garre[1*], Patricia Armero i Jurado[1], David Calviño[2] and Raul Zornoza[1]**

*[1] Universidad Politécnica de Cartagena (ETSIA), Paseo Alfonso XIII, 48, 30203 Cartagena, Spain*

*alberto.garre@upct.es

**ABSTRACT**

Soil biodiversity is key for multiple soil ecosystem services. However, soil thousands of species interact within soils. Current uncertainties on these mechanisms hamper the definition of effective measures to maintain soil health. This study presents a data-driven methodology where species interactions and their links with ecosystem services are inferred from experimental data. We use a dataset including over 180 samples from agricultural soils across Continental, Atlantic, Mediterranean, Nemoral, Pannonian, Lusitanian, Boreal and Atlantic pedoclimatic regions. Biodiversity was measured by metataxonomic analysis of bacteria (16s rRNA), fungi (ITS) and nematodes (ITS). Ecosystem services were evaluated based on physicochemical variables linked to (I) carbon sequestration and storage, (II) nutrient cycling and fertility, (III) water retention, (IV) water infiltration and erosion reduction, and (V) contamination reduction.

Based on co-abundance networks, we identified communities of closely related taxonomic units using *spin glass*. It was hypothesized that network communities represent ecosystems within the soil, which might be involved in ecosystem function regulation. Communities consistently include interactions between kingdoms (bacteria, fungi and/or nematode), demonstrating the complexity of soil ecosystems. Using sparse projection to latent spaces (*sPLS*), we identified communities relevant for nutrient cycling and fertility across every pedoclimatic region, carbon sequestration and storage in every region but Atlantic, water retention in the Mediterranean region, water infiltration and erosion reduction in Atlantic and Lusitanian regions, and contamination reduction in Mediterranean regions. Their role in these ecosystem services was verified post-hoc using data from the scientific literature that included *in vitro* or molecular analyses.

Therefore, this study presents a paradigm shift both in the computational methods for the analysis of soil ecosystems, as well as in the interpretation of soil biodiversity. Rather than focusing on key species as providers of ecosystem services, this study advocates for the characterizing biological communities whose interaction regulate soil ecosystem services. This advances our understanding of soil ecology and might, in the long term, improve measures for assuring soil ecosystem services.

# Biochar-Compost Interactions: Impacts on Soil Health and Plant Performance in Regenerative Organic Systems

**Dinesh Panday[1,*], Jarod A Pokorny[2], Jack W Monahan[2], and Christopher W Habeck[2]**

[1]*Rodale Institute, Kutztown, PA, United States*

[2]*Environmental Science Program, Biology Department, Kutztown University, Kutztown, PA, United States*

* E-mail: dinesh.livingsoil@gmail.com, dinesh.panday@rodaleinstitute.org

**ABSTRACT**

Biochar, a carbon-rich material produced from organic biomass, has been shown to improve soil structure, enhance water retention, and stimulate microbial activity. When combined with compost, its effectiveness is often amplified. However, key knowledge gaps remain regarding optimal application rates, long-term effects, and interactions across soil types and crop species. We investigated the impact of biochar, alone and in combination with compost, on soil health and sweet pepper (*Capsicum annuum* L.) growth and fruit production under controlled glasshouse conditions at Kutztown University, Kutztown, Pennsylvania, United States in summer 2025. A pot experiment was conducted using silt loam soil collected from a certified regenerative organic field at Rodale Institute, with three rates of biochar (0, 12.4, and 24.8 t $ha^{-1}$) and two rates of compost (0 and 12.4 t $ha^{-1}$), arranged with seven replications. Sweet pepper plants were grown in 28 cm tall and 25 cm wide pots after treatment application. Data collection included soil chemical properties, soil health indicators, carbon fluxes and pools, and plant growth responses. Findings from this study will support the best practices for integrating biochar and compost into regenerative organic systems to improve soil fertility, crop resilience, and productivity. Detailed results will be presented at the 23rd World Congress of Soil Science Conference.

# Soil Enzyme Activities and Microbial Biomass Biomarker Associated with the Integration of Cereal Rye to Improve Tomato Soil-Borne Disease Suppression and Yield

**Nicola Lorenz[1*], Ye Xia[2], Wenshan Liu[2], and Richard P. Dick[1]**

[1] *The Ohio State University, School of Environment and Natural Resources, Columbus, Ohio, United States of America*

[2] *The Ohio State University, Department of Plant Pathology, Columbus, Ohio, United States of America*

*E-mail lorenz.64@osu.edu

**ABSTRACT**

Agronomic management systems for improving soil and tomato health are needed for sustainable tomato production. The goals of this research study are based on the integration of holistic and ecologically sound agricultural management components, which include arbuscular mycorrhizal fungi (AMF) and cover crop (rye grass) to enhance soil health and tomato soil-borne disease control. A 3-year field experiment was conducted at The Ohio State University's Waterman Farm in Columbus/Ohio/USA on tomato growth using 2 main plot treatments: 1) rye cover crop, 2) *Fusarium* disease inoculation, and 3 split-plot treatments: a) AMF inoculation, and b) fungicide application, c) untreated control.

Soil samples were collected from the tomato root zone in 0 to 20 cm depths and were analyzed for microbial Ester-Linked Fatty Acid Methyl Esters (EL-FAME), as well as soil enzyme activities such as arylsulfatase, β-glucosaminidase, acid phosphatase, and glucanase activities. Arylsulfatase and β-glucosaminidase enzyme activities increased during the season and appear to be sensitive indicators for cover crop management and *Fusarium* disease suppression. EL-FAME analysis revealed that soil microbial biomass was stimulated by cover crop treatment, and AMF increased due to cover crop and reduction in *Fusarium* infection, indicating these treatments have induced disease suppressive soils.

# Soil Health Bioindicators: Sequences to Services across Europe for wide-scale monitoring

**Giles M. Ross[1*], Wim van der Putten[3], Justine Lejoly[1]**

[1] *Netherlands Institute of Ecology, The Netherlands*

*E-mail : g.ross@nioo.knaw.nl

**ABSTRACT**

Soil biodiversity is a primary driver of soil health, yet there is a need for a systematic pipelines to convert raw information into decision-ready indicators. Here, I present the findings of the EU HORIZON project: SOB4ES project. This is a European consortium of 15 partners with the principal aim to link soil biodiversity with ecosystem services at continental scales. Comprehensive soil biodiversity sampling from over 430 sites across nine Pedo-climatic zones was carried out between Oct-Dec 2023. In processing samples, we use AI machine-learning computer vision and verification of microbial and faunal based eDNA data analysis, we develop an end-to-end framework that translates multi-taxa sequencing outputs into functional bioindicators linked to ecosystem services.

I present findings of spatial distribution patterns across regions, land-uses and management practice intensity. By doing so, we can infer the driver of biotic groups and their interactions with abiotic parameters. We assessed total soil biodiversity across the trophic web from macrofaunal earthworms, mesofaunal microarthropods and enchytraeids, to microfaunal nematodes and protists, to microbiomes. To support application at scale, we align the biodiversity data with environmental parameters and aid determination of the resolution and aggregation required for monitoring.

Early findings indicate contrasting patterns of physical and chemical drivers and influencers across land-use types, depending on abiotic factors modifiable by the environment, and ii) those by biotic interactions. Other outcomes including potential presence/absence for certain functional biotic groups may be practical recommendations for wide-scale monitoring across land-use types. We also highlight biodiversity hotspots with potential conservation focus. Ultimately, these will inform regulatory reporting and conservation planning in both agricultural and natural ecosystems.

# A Next-Generation Approach to Soil Health in Brazil

**Glacy Jaqueline da Silva[1*], The Napi Agrogenomics – Soil Microbiome Research Network[2]**

[1] *Biotechnology Applied to Agriculture Department, Paranaense University, Toledo, Brazil*

[2] *NAPI Agrogenomics – Soil Microbiome Research Network, Fundação Araucária and SETI – Government of the State of Paraná, Brazil*

*glacyjaqueline@prof.unipar.br

**ABSTRACT**

Soil health is a central component of agricultural sustainability and global climate mitigation strategies. However, critical knowledge gaps remain in the integrated understanding of soil microbiomes across highly productive regions of the Global South. The NAPI Agrogenomics: Soil Microbiome Program emerges as the largest and most comprehensive initiative ever undertaken in these countries, combining *shotgun* metagenomics, spectroradiometry, remote sensing, and chemical, physical, and biological analyses, including emerging contaminants, to characterize microbial biodiversity and function across 12 million hectares of agricultural lands in Paraná State, Brazil. The project will conduct semi-annual sampling over five years, totaling approximately 8,000 analyses and covering both mineral soil and the plastisphere.

Grounded in literature emphasizing the role of soil–climate–microbe interactions in nutrient cycling, carbon stabilization, and resilience (Banerjee et al., 2023), the project also addresses emerging contaminants like microplastics, which alter soil microbial structure (Zhang & Liu, 2022). AMR genes will be monitored via metagenomics, following One Health principles. The first sampling (completed June 2026) followed edaphic, climatic, and productivity criteria, enabling precise spatial microbial characterization. The resulting dataset will feed machine-learning models to estimate soil health, carbon stability, management and pesticide impacts, and AMR patterns, supporting an open platform for farmer-focused recommendations.

Unprecedented in scale, temporal depth, and technical integration within the Global South, the NAPI Agrogenomics: Soil Microbiome Program establishes a new benchmark for multi-omics soil studies and lays the foundation for a regional digital agro-environmental atlas. The program serves as a model for scalable, data-driven soil monitoring systems in tropical agriculture. The initial results demonstrate the transformative potential of combining genomics, spectroscopy, and spatial data to enhance agricultural resilience and inform public policies grounded in scientific evidence.

# Soil organisms from multiple trophic levels regulate respiration in dryland purple soil

**Zhiyuan Yao[1*], Tao Wang[1], and Bo Zhu[1]**

[1] *Institute of Mountain Hazards and Environment, Chinese Academy of Sciences, Chengdu, China*

*yaozhiyuan298@foxmail.com

**ABSTRACT**

Increasing soil organic carbon (SOC) content in cropland is essential for sustainable crop production, as it optimizes nutrient cycling and mitigates greenhouse gas emissions. However, SOC sequestration efficiency is primarily constrained by soil respiration, a process driven by diverse soil organisms. To investigate their regulatory roles, a long-term field experiment was conducted to compare four treatments: no fertilizer (CK), synthetic fertilizer (NPK), partial synthetic nitrogen replacement with pig slurry (OMNPK) or crop residue (RSDNPK). We measured *in-situ* $CO_2$ fluxes and characterized the soil organisms from multiple trophic levels (nematodes, protists, fungi, bacteria) via amplicon sequencing. A complementary incubation experiment with increased labile carbon addition (CN0, CN10, CN50 and CN100) was conducted to further explore the functional gene-level mechanisms. Results showed that soil respiration was the dominant contributor to global warming as indicated by the high quantity of $CO_2$ emissions, with the RSDNPK treatment exhibiting the highest values. Multi-trophic community of key functional guilds underlying $CO_2$ emissions varied significantly among treatments. They explained up to 35% of the variation in $CO_2$ fluxes from soil and were significantly influenced by protists. The incubation experiment revealed that high labile carbon input increased soil respiration, but reduced the alpha diversity of protists, fungi and bacteria by 21-80%, alongside weakened cross-trophic interactions. The composition of carbon-cycling genes was positively correlated with soil respiration, with 23 key functional genes identified mainly for decomposing of hemicellulose, cellulose, lignin and starch. A ranking analysis indicated that bacterial and protist biodiversity were the top two factors in moderating these decomposition pathways underlying soil respiration. In conclusion, preserving multi-trophic biodiversity, particularly of bacteria and protists, is essential to mitigate excessive soil respiration. Therefore, agricultural management practices should aim to maintain balanced carbon inputs to support a diverse soil food web, thereby promoting more efficient soil carbon sequestration.

**ABSTRACT**

Amazonian soils harbor exceptionally high fungal biodiversity, critical for plant health and ecosystem functioning. This study, conducted in the Kichwa indigenous territory of Sarayaku (Ecuador) along the Bobonaza River in the Napo moist forest ecoregion, documents soil fungal communities across a successional chronosequence. Twenty-five soil samples were collected from three ecosystem types: primary forest (11 samples), secondary forest (7), and traditional chakra agroforestry systems (7). Using environmental DNA (eDNA) metabarcoding, a total of 5,172 fungal OTUs were identified, including 381 arbuscular mycorrhizal (AM) OTUs (40% unknown, likely undescribed) and 39 ectomycorrhizal (EcM) OTUs (10% unknown). Overall fungal diversity was highest in primary forests (–3,600 OTUs) and lowest in chakras (–2,400), with rapid recovery in secondary forests, underscoring the resilience of the chakra system. AM fungal richness being significantly higher in primary forests (298 OTUs) than in chakras (137), although community composition did not differ significantly. EcM richness showed no significant variation across ecosystems (9–13 OTUs per habitat). Soil factors strongly influenced diversity: high nitrogen, low pH, and elevated aluminum, iron, and copper levels were associated with reduced AM and EcM diversity, likely linked to short-term effects of slash-and-burn in chakras. RSCI analysis highlighted rare, potentially endemic taxa such as Russula aucarum. These results provide a critical baseline for long-term monitoring and data-driven restoration, demonstrating that indigenous chakra practices support the preservation and rapid recovery of high mycorrhizal diversity. Such traditional systems offer valuable models for global regenerative agriculture. Future work should include longitudinal studies and sampling of sacred sites to further explore mycorrhizal interactions and potential alleviation of metal toxicity in acidic soils.

**ABSTRACT**

Plants release amino acids and other compounds that shape rhizospheric bacterial communities, potentially enriching auxotrophic bacteria that cannot synthesize certain amino acids and depend on external sources. We hypothesize that auxotrophs are more abundant in the maize rhizosphere than in bulk soil. To test this, we used a dependency-based cultivation strategy to evaluate auxotrophy profiles in maize rhizospheric and bulk soil communities obtained from a mesocosm experiment conducted in a greenhouse for 50 days. Soil suspensions were inoculated into enrichment media prepared as minimal formulations containing only minerals and two carbon sources (pyruvate and glucose). These media were supplemented with amino acids and vitamins, organized into six chemical groups based on their structural features. The suspensions were added at $10^{-2}$, $10^{-4}$, and $10^{-6}$ dilutions, and only the latter two dilutions allowed clear discrimination of growth responses as a function of the amino acids supplied. Rhizospheric communities preferentially consumed aliphatic non-polar, polar and negative, and polar non-charged groups, while bulk soil communities favored aliphatic non-polar, polar and positive, aromatic, and polar non-charged compounds. Both environments strongly utilized aliphatic non-polar amino acids such as methionine, a described cooperative metabolite. Lysine and phenylalanine, also described as cooperative amino acids, were more associated with consumption in bulk soil. We are currently isolating auxotrophic bacteria from these enrichment cultures, and subsequent metabolomic analyses will elucidate metabolic dependencies and their roles in plant–microbe interactions.

## ABSTRACT

Microbial communities are key indicators of soil ecological functioning and respond sensitively to both land-use systems and contaminant pressures. Heavy metals such as Cd and Cr can disrupt microbial community structure, suppress functional diversity, and impair nutrient-cycling processes; however, the magnitude of these effects is strongly modulated by soil properties and management history. This study evaluates whether a more conservative agricultural system, characterized by long-term no-till and diversified cover-crop mixtures in soybean-maize rotations, confers greater resilience of the soil microbial community to metal contamination compared with its native forest and the same soil under the same crop rotations with limited cover-crop diversification.

Soils were incubated for 45 days under three treatments: control, Cd (3 mg $kg^{-1}$), and Cr (150 mg $kg^{-1}$). These metal doses align with Brazilian regulatory limits and represent environmentally relevant contamination. Bacterial communities were profiled via 16S rRNA gene (V4) sequencing following DNA extraction with the PowerSoil Pro Kit. Alpha-diversity (richness, Shannon, Simpson) and beta-diversity (Bray-Curtis PCoA) metrics were quantified and statistically evaluated to determine management-specific microbial responses. Contrary to expectations, neither Cd nor Cr significantly altered microbial diversity or community composition. Alpha-diversity remained stable across treatments within each management system, indicating that microbial richness and evenness were unaffected by metal addition. PCoA results reinforced this pattern: within each management system, control, Cd, and Cr treatments clustering together with no detectable shifts in community structure. The lack of treatment effects is consistent with rapid sorption and transformation of Cd and Cr into less bioavailable forms, especially given that Cr was added as the less reactive $Cr^{3+}$ species. Moreover, both agricultural soils were well-managed, chemically fertile, and exhibited high soil health indices, conditions known to enhance functional redundancy and buffer microbial communities against short-term disturbances. Despite their total concentration, these results show that the metals were not sufficiently bioavailable to cause short-term disruptions in soil microbial community.

# The role of microorganisms in changing the properties of eroded soils

**T. Gracheva[1]*, V. Demidov[2]**

[1] *Department of Soil Biology, Lomonosov Moscow State University, Moscow, Russia*

[2] *Department of Erosion and Soil Conservation, Lomonosov Moscow State University, Moscow, Russia*

*E-mail tanyadunaeva12@mail.ru

**ABSTRACT**

The paper presents the results of research on the influence of erosion processes on the agrochemical and microbiological properties of the soil in different seasons of the annual cycle. The objects of the study are sod-podzolic (Umbric Retisols (Abruptic)) and agro-gray (Greyzemic Phaeozems (Albic)) soils of varying degrees of erosion (Moscow region).

It has been established that the degradation of the physical and agrochemical parameters of sod-podzolic soil, which occurs as a result of erosion processes, leads to a change in microbiological parameters. A decrease in the abundance and species diversity of fungi and actinomycetes occurs with an increase in the degree of soil erosion. Significant differences were found in the taxonomic composition of microbial communities of unwashed and washed-away soils: the Sorensen species similarity coefficient does not exceed 0.42 for fungi and 0.30 for actinomycetes. Taxonomic units of mycelial microorganisms have been identified. Among fungi, these are representatives of the genera *Aspergillus*, *Cladosporium* and *Scopulariopsis*, and among actinomycetes, by *Streptomyces malachitospinus*, *S. candidus* and *Micromonospora aurantiaca*.

Investigations carried out on agro-gray soil showed that the content of alkaline hydrolyzable nitrogen, exchangeable potassium and mobile forms of phosphorus depended both on the degree of soil washout and on seasonal fluctuations. Analysis of the chemical composition of soil organic matter showed that in the summer there was an increase in carboxylic, carbonyl and aromatic components, and in other periods of carbohydrate fractions. In the agro–gray soil, bacterial biomass reserves varied from 27 to 96 kg*ha$^{-1}$, fungal biomass from 10 to 357 kg*ha$^{-1}$. The dynamics of the number of bacteria in the agro-gray soil was determined to a greater extent by the degree of washout (56% of the total dispersion) than by the season (36%). The abundance of bacteria and actinomycete mycelium decreased in the range: non-washed>slightly washed>medium washed. The annual average values of prokaryotic biomass decreased from 76 kg/ha in non-washed, to 56 kg/ha in slightly washed and 41 kg/ha in medium washed. Losses of prokaryotic biomass relative to non-washed soil were to 26% in slightly washed and 46% in medium washed soil. With an increase in the degree of washing, both fungal and bacterial biomass decreased in the range of non-washed>slightly washed>medium-washed. Washed-away soils lost an average of 50% of bacterial and 59% of fungal biomass relative to non-washed soils. In the studied soils, the level of potential respiration (SIR) exceeded the level of actual respiration (BR) by 2-33 times.

*adriano.sofo@unibas.it

**ABSTRACT**

Soil cyanobacteria are increasingly recognized as key drivers of sustainable agriculture thanks to their wide range of ecological functions. These ancient, photosynthetic microorganisms participate actively in biogeochemical cycling, enrich the topsoils with organic matter, and supply essential nutrients that support plant development. By producing extracellular polymers and diverse bioactive metabolites, they help create stable microhabitats, improve soil structure, and foster synergistic interactions with both the rhizosphere and other beneficial soil microbes. Their presence is therefore tightly linked to soil resilience, fertility, and long-term ecosystem functioning.

This study investigated the taxonomic composition and functional potential of soil cyanobacterial communities in a Mediterranean olive (*Olea europaea* L.) orchard in a semiarid, hilly area of Ferrandina (Basilicata Region, southern Italy). The orchard has been managed for over twenty years under two contrasting systems: sustainable ($S_{mng}$) and conventional ($C_{mng}$), which differed markedly in soil tillage and cover, crop residues management, fertilization and irrigation. Cyanobacteria were sampled across several representative topsoil locations (0-5 cm depth) within the orchard, and then cultured and isolated on selective nitrogen-enriched media and, to promote the growth of diazotrophic strains, on nitrogen-free media.

Sustainably managed soils hosted significantly higher cyanobacterial populations ($0.408 \times 10^2$ g$^{-1}$ soil in $S_{mng}$ vs. $0.240 \times 10^2$ g$^{-1}$ in $C_{mng}$), as counted by the densitometric and MPN methods. Light microscopy and 16S rRNA metagenomic analyses revealed clear compositional differences between systems. In the $S_{mng}$ plots, genera such as *Anabaena* and *Nostoc*, known for their nitrogen-fixing ability and ecological versatility, were more abundant and contributed substantially to community structure. Management also affected cyanobacterial metabolic profiles: cyanobacteria from the $S_{mng}$ soils showed an upregulation of the biosynthetic pathways associated with secondary metabolites, including alkaloids, phenylpropanoids, phytohormones, phytoalexins, polyketides, and terpenes, which are widely recognized for their roles in plant growth promotion and defense activation.

Overall, the findings demonstrate that sustainable soil management enhances both the diversity and functional capacity of soil cyanobacteria. These microorganisms emerge not only as crucial contributors to ecological processes and biodiversity maintenance but also as promising natural allies for improving soil health and crop productivity, two fundamental ecosystem services that were markedly higher in the $S_{mng}$ system compared with the $C_{mng}$ one.

# Permanent vegetation cover as a strategy to enhance soil multifunctionality in perennial crops in the Mediterranean basin

**Cristina García-Hernández[1,2], Alicia Morugán-Coronado[1,2*], Rubén Beltrí[1,2], Elena Sampér-Perez[1,2], Miriam Valverde-Montoya[1,2], Isabel Giménez[1,2], Elena Heredia[1,2], Eva Lloret[1,2], María Dolores Gómez López [1,2], Raúl Zornoza[1,2]**

## ABSTRACT

Agricultural intensification in the Mediterranean basin has led to soil degradation, compromising its ability to perform essential functions, creating a need for sustainable strategies. This study assessed the use of vegetation cover on the alleys of perennial crops compared to conventional tillage on soil multifunctionality in three woody crops: almond, olive and fruit trees. To evaluate multifunctionality, we used the following categories: i) soil quality by visual soil assessment; ii) nutrient cycling; iii) organic matter decomposition; iv) plant productivity (biomass of vegetation); and v) plant health (estimated by the abundance of microorganisms potentially producing siderophores). Multifunctionality was assessed by using three indices (Z-scores, thresholds, and clusters). Finally, differences and the impact of different biotic and abiotic properties on the multifunctionality index were evaluated. The three indices showed similar results. Farms with vegetation covers showed higher multifunctionality index than those with tilled alleys, as reflected by the z-score (0.178 ± 0.450 and -0.178 ± 0.308), threshold (0.450 ± 0.394 and 0.308 ± 0.313) and cluster indices (0.187 ± 0.435 and -0.187 ± 0.301). The results obtained showed that the abiotic factors temperature and cover crop year increased the multifunctionality index. Increases in soil clay content, bulk density, calcium carbonate, pH, altitude, and tillage depth led to a decrease in multifunctionality. Furthermore, we found a negative relationship between soil microbial diversity with the multifunctionality index, estimated using Pielou's evenness for fungi and bacteria and the Shannon index for fungal diversity. In conclusion, although certain abiotic soil properties may improve multifunctionality, higher microbial diversity did not translate into greater multifunctionality in Mediterranean systems. This suggests that, in this region, assessing the functional composition of microbial communities may provide more meaningful insights than focusing exclusively on overall biodiversity. Moreover, the transition to systems with permanent vegetation cover in alleys is presented as an effective strategy to decouple agricultural production from soil degradation, with the duration of vegetation cover, tillage, climatic conditions, clay content, pH, carbonate and bulk density being key factors in maximizing multifunctionality in Mediterranean agroecosystems.

# Phosphate-Solubilizing Bacteria Enhance Sugarcane Growth: High-Potential Candidates for Sustainable Biofertilizer Development

**Pechrada Pinjai[1*], Wittaya Thawornsak[1] and Chatraporn Thongponkaew[2]**

[1] *Department of Soil Science, Kasetsart University, Bangkok, Thailand*

[2] *Department of Agriculture,* Ministry of Agriculture and Cooperatives, *Bangkok, Thailand*

*pechrada.j@ku.th, agrprj@ku.ac.th

**ABSTRACT**

This study selected four high-efficiency phosphate-solubilizing bacteria isolated from sugarcane cultivation areas in Sa Kaeo Province, Thailand. These strains—*Kosakonia radicincitans*, *Bacillus subtilis* OTEB25, *Bacillus subtilis* SKUAST1, and *Enterobacter* sp.—exhibited high phosphate-solubilizing activity (447–748 µg/mL) in previous research. The objectives were to determine the optimal bacterial concentration and environmental conditions for phosphate solubilization and to examine the potential of PSB to promote plant growth. The results showed that the optimal initial cell concentration for phosphate solubilization was $10^8$ CFU/mL. The bacteria were able to solubilize phosphate in culture media under both acidic and alkaline conditions with pH range of 5–9, achieving solubilization levels of 212.5–787.5 µg/mL. However, they were unable to grow or solubilize phosphate under strongly acidic conditions (pH 4.0). Among the tested isolates, *Kosakonia radicincitans* and *Bacillus subtilis* SKUAST1 demonstrated greater pH stability than the others and were therefore selected for further evaluation in sugarcane. Greenhouse experiments revealed that inoculation with these strains, either individually or in combination with rock phosphate, enhanced sugarcane growth—including plant height, fresh stalk weight, stalk length, and stalk diameter. Combined inoculation with rock phosphate significantly increased phosphorus uptake and soil available P relative to the control. These bacteria were able to survive, solubilize phosphate, and promote sugarcane growth more effectively than the control treatment. Therefore, *Kosakonia radicincitans* and *Bacillus subtilis* SKUAST1 are considered promising candidates for field-scale trials to evaluate their effects under real cultivation conditions, with potential for future development as biofertilizers.

**ABSTRACT**

Global environmental co-contamination, fueled by expanding industry and agriculture, challenges ecological restoration. Though microbial consortia outperform single strains, rational design of stable, pollutant-adaptable communities remains a microbial ecology gap. Current methods rely on empirical trial-and-error, lacking systematic integration of native microbial functions or metabolic interactions, limiting real-world remediation efficacy.

We developed a "top-down & bottom-up" framework: Top-down analysis transformed natural microbiomes into functional ones via stress acclimation, screening keystone species for synthetic communities. We also created the genome-scale metabolic modeling (GSMM) tool SuperCC (Super Community Combination), which deciphered inter-strain interactions and simulated remediation performance via bottom-up modeling. Using 18 natural keystone species, SuperCC-supported engineered microbiomes enhanced herbicide (single contamination) degradation, validating its utility. For co-contamination, we expanded SuperCC applications: Modeling 6 key strains' metabolic behaviors and integrating multi-omics clarified interaction networks. We found secretory products of broad-spectrum resource-utilizing bacteria drive interspecific synergy, and indigenous keystone strains stabilize community function. These insights led to the novel DHP-Com (Degrader-Helper-Potentiator) synthetic microbiome paradigm, where "potentiators" (species with stable habitat abundance) boost community ecological adaptability. DHP-Com-based synthetic microbiomes achieved breakthrough remediation efficiency in multi-pollutant soils, resolving unstable synthetic community function under co-contamination.

With scenario-specific SuperCC application, this study links microbiome engineering pathways from single to co-contamination. It verifies model-driven technology's applicability across pollution gradients, provides a "natural regulation to synthetic design" progressive solution for next-gen soil bioremediation, and bridges microbial metabolic modeling with practical pollution control.

[4]College of Environment and Resources, Zhejiang A&F University, Hangzhou, China

**ABSTRACT**

Ectomycorrhizal fungi (EMF) are essential for plant-soil nutrient cycling in forest ecosystems, forming symbiotic relationships with plant roots. They receive 10-30% host plant photosynthate and in return improve plant nutrient acquisition. EMF symbiosis can establish common mycorrhizal networks (CMNs), connecting multiple plant hosts from the same or different species. CMNs have been found to enhance plant productivity and crucial in carbon sequestration. However, the quantity of the resources exchanged between plants and who manipulates the exchanges remain unanswered. Therefore, it's significant to investigate CMNs role in belowground nutrient cycling and how it relates to the host species identity.

This study aims to assess 1) the significance of carbon and nitrogen transfer through CMNs between pine and bilberry, 2) whether the interaction of different plant species affect their growth performance. One-year-old seedlings of Scots pine (*Pinus sylvestris L.*) and bilberry (*Vaccinium myrtillus*) were planted in the custom-made pots, which were divided equally with three types of barriers: solid barrier (no connection), 50μm mesh (roots blocked) and no-barrier (full connection). The seedlings were planted from October 2023 to October 2024 in three combinations: pine-bilberry, pine-pine, bilberry-bilberry. Labelling with $^{13}CO_2$ and $^{15}N$-needle-litter were performed for tracing the nutrient cycling. To quantify the carbon transferred by fungal hyphae, soil microbial biomass total C and $^{13}C$ were measured, alongside the plant photosynthesis and $^{13}C$ in needles/leaves. Plant productivity was evaluated through shoot and roots biomass. Microbial carbon use efficiency was analyzed using $^{18}O$-$H_2O$ to determine SOC stabilization. under snow exclusion. To further study changes in soil microbial community, the fungal Internal Transcribed Spacer (ITS2) and bacterial 16S from the isolated DNA was sequenced by Illumina MiSeq platform.

Preliminary results will be presented in the presentation.

**ABSTRACT**

As a critical carrier for agricultural production, the stoichiometric balance between soil microorganisms and resources (carbon, nitrogen, phosphorus) in black soil ecosystems serves as the core regulatory link governing nutrient cycling and organic carbon pool stability. Tillage disturbances induced by agricultural reclamation not only alter the spatiotemporal distribution patterns of soil nutrients but also profoundly disrupt the stoichiometric coupling between microorganisms and their resources. However, existing research on microbe-resource interactions has predominantly focused on single temporal or spatial sequences, leaving the dynamic evolution of these relationships under dual spatiotemporal dimensions and the underlying microbial adaptation mechanisms insufficiently addressed. This study investigated black soil farmlands with different reclamation ages (65, 85, and 105 years) to explore the dynamics and response patterns of microbe-resource stoichiometry across soil layers (0—50 cm). Results revealed that the C:P stoichiometric imbalance between microorganisms and their resources significantly intensified with increasing reclamation age, with the most pronounced effects observed in the topsoil (0–20 cm). In response to this imbalance, microbial communities exhibited a dual adaptation strategy of "homeostasis maintenance-functional adjustment": (1) the microbial biomass C:N ratio remained relatively stable with no significant fluctuations, reflecting strong homeostatic characteristics; and (2) microorganisms adjusted the vertical distribution of extracellular enzyme activities (e.g., significantly increasing the ratio of phosphorus-acquiring enzymes to carbon-acquiring enzymes in the topsoil) to acquire limiting nutrients. These findings indicate that the spatiotemporal dynamics of microbe-resource stoichiometry in black soil agricultural ecosystems are synergistically driven by the "cumulative effect of reclamation age and vertical differentiation of soil depth." Furthermore, microbial homeostatic regulation and enzyme activity optimization represent key adaptation mechanisms for sustaining ecosystem functionality. This study clarifies the evolution of microbe-resource stoichiometric balance following black soil reclamation, providing a scientific basis for soil fertility management and organic carbon pool protection in black soils across different reclamation stages and soil layers.

# Variations in synergistic benefits among different intercropping systems: evidence from crop, soil and soil biota in agroecosystems

**Minghao Yang[1,2], Ziyi Tang[1,2], Tianci Wu[1,2], Xiao Wang[1,2], Wenju Liang[1,3], and Xiaoke Zhang[1,3]***

[3] *Key Lab of Conservation Tillage and Ecological Agriculture, Liaoning Province, Shenyang , China*

*E-mail address: zxk@iae.ac.cn

**ABSTRACT**

Intercropping has been increasingly adopted to mitigate agricultural land degradation caused by long-term monocropping. It leverages the synergistic traits of different plant species to optimize aboveground and belowground resource utilization, thereby significantly enhancing agricultural productivity and ensuring long-term sustainability. However, studies on the synergistic regulation mechanisms among crop, soil and soil biota remain scarce in different intercropping systems. To elucidate how intercropping systems modulate crop-soil-soil biota, both peanut/maize and alfalfa/maize combinations were selected to determine and compare crop growth performance, soil characteristics, and key soil nematode metrics including their abundance, community composition and food web energy structure. Studies have shown that peanut/maize intercropping resulted in a higher land equivalent ratio and significantly increased soil nitrogen levels compared with alfalfa/maize intercropping. Both intercropping systems increased soil nematode abundance compared with monocropping. Meantime, the richness, diversity, maturity and structure indices of soil nematode communities were enhanced in the maize rows of both intercropping systems. Furthermore, intercropping also altered carbon flux dynamics and improved the uniformity of carbon flux within the soil nematode food web in the peanut rows. Partial least squares path modeling revealed that peanut/maize systems improved soil nematode communities through direct and indirect pathways by enhancing crop competitiveness and optimizing soil properties, whereas alfalfa/maize exhibited weaker effects. In conclusion, the peanut/maize system exhibited both strong selection effects aboveground and complementarity effects belowground, as evidenced by the improved soil characteristics and the amplification of ecological regulation pathways among crop, soil, and soil biota. Peanut /maize intercropping was shown to generate significant aboveground and belowground synergies which both boost crop yields and maintain optimal system productivity, providing a cost-effective and sustainable intensification strategy for modern agroecosystems.

## ABSTRACT

Barley-pea intercropping has the potential to restructure soil microbial communities and nutrient cycling functions, with responses shaped by soil compartment, management system, and year. We quantified the abundance of microbial taxonomic markers (bacterial and archaeal *16S rRNA* genes, fungal *ITS*) and key nitrogen cycling genes (*nifH,* archaeal and bacterial *amoA*, *nirK, nirS*, *norB*, *nosZ*) in rhizosphere and bulk soils over two growing seasons under conventional and organic management with and without manure, within a long-term crop-rotation experiment established in 1997.

A clear pattern emerged in which archaeal groups, archaeal *amoA*, and total fungi showed the strongest and most consistent responses to crop treatments. In the rhizosphere, intercropping and legume monoculture frequently elevated archaeal 16S and archaeal *amoA* abundances across both years, particularly in organic systems, indicating a strong recruitment or enrichment of ammonia-oxidizing archaea by plant roots. Fungal *ITS* abundance was also consistently increased by legumes and intercropping, both in the first year across management systems and in the second year under organic management with manure. Denitrification-related genes exhibited more targeted shifts, including higher *nirK* in legume treatments in the first year under conventional management and elevated *norB* under intercropping in organic systems with manure. Conversely, *nifH* declined under legumes in the second year in organic systems without manure, suggesting limitations on free-living nitrogen fixation under certain nutrient contexts.

Bulk soil responses diverged from those of the rhizosphere and were strongly year dependent. In the second year under conventional management, intercropping and legumes increased archaeal and bacterial *amoA*, while fungal *ITS* and bacterial *16S* were elevated in the first year. Some functional genes declined in bulk soil under intercropping, including *nosZ* in organic systems without manure.

Overall, barley-pea intercropping significantly restructured soil microbiomes, with the strongest and most consistent effects seen in ammonia-oxidizing archaea and total fungi. These findings suggest that plants and their associated soil environments selectively recruit microbial groups that enhance specific nutrient cycling functions, especially nitrification and fungal-driven resource turnover. The results demonstrate that crop diversification acts as a biological filter shaping microbial communities and functions, but the magnitude and direction of these effects depend on soil compartment, nutrient management, the long-term rotation context of the site and interannual variability.

**ABSTRACT**

Mining and quarry activities have significant environmental impact on ecosystems over the years, especially when these activities are abandoned. Among others, new soils can form over mine wastes characterized by imbalanced texture classes or chemical properties or high contents of heavy metals in the soils and in surrounding waters. In general, to assess the success of different reclamation activities, physicochemical properties are evaluated; however, few studies have focused on biological properties. In this study, we selected soils from unreclaimed and reclaimed areas in Spain: a Cu abandoned mine area (NW Spain) and a Pb/Zn mine area (SE Spain). In both cases, mining activities were abandoned several decades ago. Remediation activities have been applied several years after abandonment. They were focused on the creation of artificial soils (Technosols) by using the aided phytostabilization technique, which combines heavy metal-tolerant plants (rhyzostabilization) with organic or inorganic amendments (chemical stabilization), aiming to reduce soil metal bioavailability while improving soil health. Soil samples (0-30 cm depth) have been collected from both reclaimed and unreclaimed areas, and physical, chemical, and biological properties have been measured. In general, soil physicochemical properties have improved after reclamation, including reduced bioavailable metal concentrations (Cu, Pb, Zn). In the case of biological properties, changes in the soil microbial community have been assessed using phospholipid fatty acid (PLFA) analysis. The Phospholipid Fatty Acid (PLFA) analysis revealed that the microbial community improved after amendments and was aided by phytostabilisation activities. In both restored mining areas, the biomass of Total PLFAs, Bacteria (including Gram+ and Gram-), and Fungi (Arbuscular mycorrhizal fungal, Zygomycota, and Ascomycota/Basidiomycota groups) was significantly higher than in non-restored areas ($p < 0.05$, t-test). These groups exhibited a 4–10-fold increase in biomass following restoration. However, the differences in Fungal/Bacterial and Gram+/Gram- ratios between treatments were not significant at the treatments carried out in the Cu mine. In general, reclamation activities improved soil physicochemical and biological properties in both abandoned mining areas, highlighting the potential of technosols and aiding phytostabilisation to reduce environmental impacts.

# Conservation Tillage Reduces Mycotoxin Contamination in Black_Soil Maize Systems

**Mengtian Chen**[1], **Hu Zhou**[1*]

[1] *College of Land Science and Technology, China Agricultural University, Beijing, China*

**Hu Zhou, E-mail: zhouhu@cau.edu.cn*

**ABSTRACT**

Maize mycotoxins represent a persistent global challenge to crop productivity, food safety, and public health. Tillage strongly shapes soil physicochemical conditions and microbial communities, thereby influencing the occurrence of toxin-producing fungi and mycotoxin accumulation. Although no-till is prevalent in the black soil region of northeastern China, its impact on maize mycotoxin contamination remains insufficiently understood. In this study, we combined a 14-year tillage experiment with multi-site field surveys across six farms in Jilin Province to evaluate maize kernel mycotoxins and soil fungal communities under conventional tillage (CT) and no-till (NT). Fourteen major mycotoxins were quantified using LC–MS/MS, among which deoxynivalenol (DON) and zearalenone (ZEN) were consistently detected across all samples over the two study years. NT markedly reduced the exceedance rates of DON and ZEN compared to CT. Moreover, NT enhanced fungal α-diversity, shifted community composition, and increased several ecologically important functional groups, indicating greater soil microecosystem stability. Overall, our study provides multi-site field evidence that NT lowers mycotoxin risks and promotes a more diverse and resilient soil fungal community. This supports the conclusion that NT is a sustainable management practice in black soil agroecosystems.

**ABSTRACT**

Conversion of agroforestry systems to conventional agriculture is increasingly practiced in Southern Ethiopia due to rising food demand and economic pressures. This land-use change has critical implications for soil health, particularly concerning soil biota and microbial biomass carbon (MBC), which are key indicators of soil fertility and ecological sustainability. This study investigated the effects of agroforestry-to-agriculture conversion on soil biological properties at selected sites in Southern Ethiopia. Paired soil samples were collected from long-established agroforestry plots and adjacent agricultural lands that had been converted from agroforestry. Soil biota diversity and abundance were assessed, and microbial biomass carbon was measured using the chloroform fumigation-extraction method. The results showed a significant reduction in both MBC and soil faunal abundance following conversion. Agroforestry plots exhibited substantially higher MBC levels and greater diversity and abundance of soil organisms, including macrofauna and mesofauna. These differences are attributed to higher organic matter inputs, better moisture retention, and more stable microclimatic conditions in agroforestry systems. The findings emphasize that agroforestry systems support soil biological health more effectively than conventional agriculture. The loss of microbial biomass and soil biodiversity following conversion may impair soil functions such as nutrient cycling, organic matter decomposition, and long-term productivity. Overall, while the conversion of agroforestry systems to agriculture may provide short-term gains in food production, this trade-off is offset by the decline in soil quality and ecological resilience. Maintaining or integrating agroforestry within agricultural landscapes offers a more sustainable pathway that balances productivity with the preservation of soil health and ecosystem services, which is particularly vital in regions at risk of land degradation and food insecurity.

# Effects of Crop Residue Management Strategies on Soil and Root Nematode Assemblages

**Md Niraul Islam[1], Yingbin Li[1], Xiaofang Du[1], Qi Li[1]**

*Institute of Applied Ecology, Chinese Academy of Sciences, Shenyang, China*

*mnislam15@gamil.com

**ABSTRACT**

Crop residues play a crucial role in maintaining soil health by enhancing organic matter, nutrient cycling, and microbial activity, thereby improving soil structure, water retention, and nutrient availability for sustainable maize production. Nematodes occupy multiple trophic levels and respond sensitively to environmental change, making them reliable bioindicators of soil quality and soil food-web condition. However, the effects of crop residue management on nematode communities differ between rhizosphere soil and root endospheres, and these compartment-specific dynamics remain poorly understood. Understanding these differences is essential for linking residue management to soil food-web functioning and plant health. A field study evaluated six residue management strategies: control (CK), no-tillage (NT), straw deep incorporation (SD), biochar (BC), and their combinations (NTBC, SDBC), to determine their effects on nematode community structure, diversity, and ecological indices in a maize agroecosystem over two consecutive growing seasons. A total of 64 nematode genera representing 40 families were identified across all treatments, enabling a comprehensive assessment of trophic and taxonomic responses. The rhizosphere soil sustained richer and more functionally diverse nematode assemblages, dominated by *Acrobeloides* and fungivores, with NTBC showing the highest Shannon diversity (H') and food-web complexity. Generic richness, taxonomic diversity, maturity index, and structural index were consistently higher in soil than in roots, indicating a more structured and resilient soil food web. In contrast, root habitats were low in diversity and dominated by *Ditylenchus*, which comprised up to 86% of the community, reflecting strong plant-parasitic pressure within root endospheres. Soil moisture, organic carbon, and total nitrogen were the key environmental drivers shaping nematode community structure, with fungivorous nematodes showing the strongest positive responses to improved soil conditions. Residue treatments showed clear trophic shifts: NT and NTBC enhanced fungal feeders and reduced plant-parasitic nematode abundance in roots and/or their trophic proportion in soil, whereas SD and SDBC increased the relative abundance of bacterivores and lowered overall plant-parasitic nematode indices. Dominant nematode genera served as effective ecological indicators of residue-driven changes and nematode pressure in maize. Overall, integrated residue management practices, especially NT and NTBC, promoted a structured and resilient soil food web while mitigating root pathogen pressure. These findings demonstrate that combining no-tillage with biochar incorporation offers a sustainable strategy to enhance soil ecological stability and regulate nematode communities in maize cropping systems.

# The effects of nutrient-loaded biochar on earthworms in boreal agricultural soils

**Zannatul Ferdous[1*], Samuel Amoah[1], Jure Zrim[1] and Priit Tammeorg[1]**

[1]*Department of Agricultural Sciences, University of Helsinki, Helsinki, Finland*

*zannatul.ferdous@helsinki.fi

**ABSTRACT**

Nitrogen loss from agricultural soil has led to various environmental hazards such as nitrogen (N) pollution, threatening water quality and contributing to eutrophication of aquatic ecosystems. Therefore, enhancing nitrogen use efficiency is an important approach for sustainable agriculture to meet the rapidly increasing food demand while minimising the harmful environmental effects. Nutrient-loaded biochars (NLB), a relatively recent concept, have the potential to simultaneously sequester atmospheric carbon in the soil as a means of mitigating climate change, provide slow and continuous nutrient release, and reduce nutrient loss. However, NLB's interaction with soil biota, especially earthworms, is essential to ensure the safe and efficient application of NLB in soil.

The study investigates the effect of organic nutrient-loaded NLBs on earthworm abundance, biomass, and mean weight in southern Finnish agricultural soils, loamy sand (Umbrisol). This was conducted in long-term continuous biochar field experiments at the University of Helsinki's Viikki Research Farm since 2011. NLBs were prepared from spruce biochar, activated with nitric acid and were then loaded with organic fertiliser (cattle slurry/meat bone meal). In a split-plot design, NLB treatment in Umbrisol was applied at two rates: 0 biochar and 20+30 t $ha^{-1}$. Fertiliser treatments include two types (no fertiliser and mineral fertiliser). NLB was applied to the topsoil layer in May 2023 before barley sowing in the soil. Post-harvest (2023 and 2025), earthworms were sampled from randomly selected locations within each plot using holes (25x25 $cm^2$, 28cm deep) by hand sorting and mustard extraction. Then counted, weighed, and identified based on morphological characteristics, such as pigmentation and clitellar development.

Preliminary data from the first year of application in 2023 did not indicate any significant short-term effects of NLB on the earthworm community. However, the higher application rates in loamy sand (20+30 t $ha^{-1}$) reduce earthworm biomass 1.29 g ($p=0.5$), indicating a potential threshold for safe use. A follow-up study in 2025, after two years of NLB application, now under analysis, would help to determine whether these effects persist or reduce over time. Moreover, the findings can also support climate change mitigation and ecological balance in boreal regions.

## ABSTRACT

Various pesticides are widely used products for plant protection. However, their use exposes non-target organisms to undesirable effects. To assess their effect on the soil microbial biomass and community composition, a pot experiment was conducted in the greenhouse at the University of Debrecen, Hungary during spring from 23rd April to 23rd June 2025. Three kilograms of air-dried and sieved Chernozem soil collected from Látókép research station were weighed into plastic pots. A completely randomized design with five treatments (Trichoderma (10 ml per pot at a concentration of 0.027%), Lambda Cyhalothrin (0.6 g/pot), Cypermethrin (0.6 g/pot), Tefluthrin (0.5 g/pot) and control) and four replicates per treatment were used, totalling 20 experimental units. Prior to pesticide application, each pot was supplied with 50 ml of NPK fertilizer solution, prepared by dissolving 0.1247 g of $NH_4H_2PO_4$, 0.457 g of $NH_4NO_3$ and 0.288 g of KCl in 1000 ml of reverse osmosis water. Five seeds of FAO 270 hybrid corn were sown per pot, later thinned to four seedlings after germination. Each pot was weighed daily and ion-exchanged water supplied to maintain 60% of the maximum water holding capacity. Soil samples for Phospholipid Fatty Acid (PLFA) analysis were collected at 2, 12, 19, 40 and 61 days after pesticide application. The soil microbial biomass based on total PLFA and its community composition (saprophytic fungi, Gram-positive bacteria, Gram-negative bacteria, actinomycetes, arbuscular mycorrhizal fungi, fungi to bacteria ratio and Gram-positive to Gram-negative bacteria ratio) were determined. Data were analyzed using repeated measures ANOVA to assess the effects of pesticide treatment and time on soil microbial biomass and community composition in SPSS (version 29). Results indicate that pesticide treatments did not significantly differ in overall microbial biomass and community composition ($F(4,15) = 2.17$, $p = 0.123$, $\eta^2 = 0.366$). Time had a significant effect on microbial parameters (Pillai's Trace = 0.947, $F(4,12) = 53.27$, $p < 0.001$, Partial $\eta^2 = 0.947$), indicating that soil microbial biomass and community composition changed between sampling time points. The highest microbial biomass generally was observed at 61 days post pesticide application. No significant interaction of Time x Treatment (Pillai's Trace = 0.977, $F(16,60) = 1.21$, $p = 0.286$, $\eta^2 = 0.244$) was found, indicating that pesticide application did not influence how microbes changed over time. We attribute the microbial biomass at 61 days to the high root density, which increased exudates in the soil, hence boosting microbial life. In conclusion, treatments behaved similarly throughout the study period, with no pesticide underperforming or outperforming the others. Progress of growing season, rather than pesticides applied, was the determining factor responsible for changes in microbial groups.

**Key words:** PLFA analysis, soil microbial biomass, soil-applied pesticides, corn

# Developing a Framework for Soil Microbial Indicators

**ABSTRACT**

Growers, advisers and policy makers are increasingly turning to soil biology to explain soil function, security and resilience, yet there is limited consensus on which microbial indicators to measure, how to interpret values, and how to link them to agronomic outcomes. Existing soil health frameworks typically focus on sets of chemical and physical indicators, with biological measures often added opportunistically and interpreted in isolation. This limits confidence in biological testing and constrains uptake of emerging microbial diagnostics for on-farm decision making.

A research program spanning a wide agro-climatic zone was established to develop and validate a framework for interpreting soil microbial indicators in broadacre grain systems under varied management practices. Five field experiments (cover cropping, herbicide withdrawal, alleviation of abiotic stress in calcareous soils, and regenerative versus conventional management) were monitored over two years. At each site, soils were sampled at key crop growth stages and characterized using a tiered indicator suite targeting: (1) microbial food sources, (2) microbial community structure, (3) potential microbial activity, (4) realized biological functions, and (5) agronomic and ecosystem outcomes.

The framework integrates this soil biological cycle by linking plant-derived carbon inputs and soil organic matter pools (e.g. total C/N, MIR-predicted C fractions, hot-water extractable C and N, soil C fractions, autoclave–citrate–extractable protein) with measures of "who is there" (amplicon sequencing of bacteria and fungi, qPCR quantification of agriculturally important populations, such as mycorrhizal fungi and nematodes). Potential and realized functions including soil enzyme activities, pathogen suppression, and N-cycling outcomes were also assessed and related to crop performance metrics, such as biomass and yield.

Multivariate and correlation-based analyses were used to identify linkages among indicators and to improve the interpretability and translation of meaningful biological indicators. The outcome is a scalable framework that has synthesized a wide array of biological measurements into interpretable metrics for decision-making. This framework has been translated into decision-support tools and training resources for researchers, service providers and landholders, enabling soil microbial testing to be integrated into soil health assessments across Australian grain production landscapes.

**ABSTRACT**

Sustainable cropping systems, particularly no-tillage, are known to enhance soil biodiversity and physicochemical properties. Despite these benefits, their adoption and related research remain limited in Japan, which requires field-scale trials to support their expansion. This study aimed to investigate the effects of sustainable cropping systems on soil biological and physical properties and to clarify their interrelationships.

A five-year continuous soybean field experiment was conducted at Fukushima University, Japan, using 32 plots (8 treatments with 4 replicates) combining tillage (conventional tillage vs. no-tillage), weed management (herbicide vs. no-herbicide), and fertilizer (chemical vs. organic). In July 2024, earthworm populations were sampled using hand-sorting at 0–10 and 10–20 cm depths and mustard extraction at >20 cm depths. Soil microbial biomass carbon (MBC) and nitrogen (MBN) were determined using the chloroform fumigation-extraction method. Mean weight diameter (MWD) of aggregates was determined using the wet-sieving method. Both analyses were conducted on soil samples from 0–10 and 10–20 cm depths. The carbon content of each aggregate fraction was also measured.

No-tillage significantly increased earthworm population density, particularly of the Moniligastridae family, which is less commonly reported in Japan. MBC and MBN in the 0–10 cm soil layer showed the highest values under the combination of no-tillage, no-herbicide, and organic fertilizer treatments. Among the factors tested, no-tillage was the primary factor contributing to increased soil fauna and microbial biomass. No-tillage also improved MWD, indicating enhanced aggregate stability, which led to a higher proportion of macroaggregates and increased carbon content within macroaggregates. Path analysis showed that no-tillage promotes microbial biomass by developing soil aggregates, which provide crucial habitats.

These findings highlight the no-tillage production system as a key practice for improving soil biodiversity and health. Our results also suggest the potential for the wider adoption of sustainable cropping systems in Japanese agriculture.

## ABSTRACT

**[Background and Objective]**

Conservation agriculture (CA), combining no-tillage (NT) and cover crops (CC), is increasingly adopted for sustainable farming, yet its impacts on soil biota, particularly protists and nematodes, and their functional interactions remain insufficiently understood. We investigated soil biotic communities, trophic interactions, and functional attributes under long-term CA in humid Andosols, Japan.

**[Methods]**

The study site was the long-term experimental field (>20 yr) of Andisols in Ibaraki University, Japan. Surface (0–5 cm) and subsurface (5–15 cm) soils were collected from conventional tillage (CT) and NT under low and high CC densities across three seasons. Microbial abundance was quantified by digital PCR, and amplicon sequencing profiled bacteria, fungi, protozoa, and nematodes. Along with the measure of soil physicochemical and biological properties, β-glucosidase activity (BG) was measured, and microbial C metabolic efficiency was evaluated using BG normalized to microbial biomass C (BG/MBC). Linear mixed model was used to assess the effect of each factor on targeted properties. Community composition and multitrophic networks (SPIEC-EASI) assessed treatment and seasonal responses.

**[Results and Discussion]**

Long-term NT markedly increased SOC (12.8 g kg−1), MBC (~200 mg kg−1), soil moisture (~3.5 wt%), and available N (64.6 mg kg−1) in the surface soil, whereas CT maintained higher values in the subsurface. Across seasons, NT consistently doubled MBC and microbial DNA abundances for bacteria and fungi in the surface soils, while CC effects on soil properties were minimal. All treatments remained bacteria-dominated (fungi: bacteria < 0.05), and BG/MBC ratios were comparable, indicating similar microbial C metabolic efficiency. Community structure diverged strongly by tillage: CT bacterial communities shifted seasonally, whereas NT communities were more stable throughout the year. RDA and LEfSe associated higher SOC under NT with enriched Proteobacteria and Bacteroidota, which can support protozoan predation. Multitrophic networks integrating bacteria, fungi, protozoa, and nematodes revealed that NT topsoil supported a more highly connected soil food web, with ~1.2–1.8× more edges, higher mean connectivity, and greater representation of bacterial–protozoan interactions. NT networks also exhibited lower modularity, indicating a more integrated community structure. These findings suggest that NT, rather than CC management, fosters a more cohesive and dense-linked soil biotic network, potentially contributing to enhanced C cycling in NT topsoil.

## ABSTRACT

**[Background and Objective]**

Conservation agriculture (CA), a combination of no-tillage and cover cropping, has attracted attention for its potential to achieve carbon sequestration and enhance soil biological properties. The effects of CA have been investigated mainly under long-term management (>10 years), and it is known that longer durations tend to result in clearer changes in both soil physicochemical and biological properties. To examine the short-term effects of CA, this study aimed to evaluate how five years of CA influence soil chemical properties and biological communities in a Japanese agricultural field.

**[Methods]**

The study site was the Masuzawa Field in Fukushima University, a former paddy field where CA has been implemented for five years. This site has a temperate climate, and the soils are classified as Inceptisols (brown forest soil). Soil samples were collected from four soybean cultivation plots combining two treatments—tillage vs. no-tillage and presence vs. absence of weed residues (+weed vs. -weed). Sampling was conducted in June 2024 (just after sowing) and November 2024 (just before harvest) from two soil layers (0–5 cm and 5–15 cm), with four field replications per treatment. In addition to soil chemical properties (e.g., total soil carbon), biological properties were measured. Microbial abundance (bacteria and fungi) was quantified using dPCR. β-glucosidase activity was measured as a representative enzyme activity. Biological community composition and cross-kingdom interaction networks among bacteria, fungi, protists, and nematodes were analyzed using amplicon sequencing.

**[Results and Discussion]**

Total carbon content was higher only in the surface (0–5 cm) soil of no-tillage plots compared with tillage plots (–weed: +28%, +weed: +39%), confirming the effects of no-tillage and additional weed residues on carbon accumulation in surface layers where plant residues accumulate. Regardless of sampling times, bacterial and fungal DNA copy numbers were 2.0–3.0 times higher in the surface layer under no-tillage than in tillage plots. β-glucosidase activity was also 2.3–3.0 times higher in the surface layer. These comparable increases suggest that microbial abundance may directly contribute to elevated soil enzyme activity. As for biological communities, clear no-tillage effects were observed for bacteria, fungi, and protists (but not for nematodes). In bacteria, significant increases were detected in *Bacteroidota* and *Proteobacteria*, which are often associated with r-strategists. In contrast, the weed treatment did not lead to clear changes in community composition. Network analysis revealed that bacteria-centered biological networks were strengthened in the subsurface layer of the no-tillage plots, but not in the surface layer. As the subsurface network was composed mainly of paddy-oriented biota, these effects of CA on the subsurface layer might be specific to former paddy fields. Overall, even after five years of management, CA led to increased soil carbon, higher microbial abundance, and community shifts in the surface layer, and furthermore strengthened biological networks in the subsurface.

E-mail: andre@kpu.ac.jp

## ABSTRACT

Biochar derived from acai (*Euterpe oleracea*) seeds offers a sustainable option to valorize acai production residues, which otherwise accumulate in high volumes and contribute to fungal disease proliferation in field disposal. We hypothesized that amending soils with acai-seed biochar can enhance soil carbon (C) sequestration, improve phosphorus (P) availability through enhanced P-solubilizing microbial activity, and shift the soil microbial community toward beneficial taxa. To test these hypotheses, we conducted a controlled incubation experiment using soils representative of major Brazilian biomes (Amazon — acai-cultivated and native, Cerrado, Atlantic Forest, Semi-arid Caatinga), with and without 10% (w/w) acai biochar addition. Soils (250 g) were incubated in the dark at 25 °C for six months, with sampling at 0, 3, and 6 months. Chemical analyses included total and available P, amorphous Fe and Al, total C and N, C/N ratio, and pH. Biological analyses comprised the bacterial and fungal community profiling via metagenomic sequencing. Biochar amendment significantly increased available P — particularly in Amazon and Cerrado soils — and enhanced total C and the C/N ratio across all soils. Metagenomic data revealed an increased relative abundance of beneficial fungal genus (e.g., *Trichoderma*) in Amazon Native and Acai soils amended with biochar after three- and six- months incubation. There was positive correlation between this fungal genus and available P, even though statistically non-significant. These findings can support that acai-seed biochar improves soil fertility and some fungal groups more locally and individually than at general scale.

**ABSTRACT**

Global mining activities have impacted vast downstream regions through heavy metal accumulation, significantly altering soil microbial communities and enriching antibiotic resistance genes (ARGs) via co-selection with metal resistance genes. Mining environments have been recognized as important reservoirs of ARGs, yet their potential migration into surrounding ecosystems and associated risks remain poorly understood.

Here, we conducted a national-scale investigation, analyzing 416 soil metagenomes to comprehensively characterize the mining resistome and its migration potential. We found that mining soils were enriched in bacitracin resistance genes. Host analysis revealed that 60% of ARG-carrying genomes (ACGs) detected in downstream farmland were shared with those from mining sites. Source tracking indicated that 57% of quinolone resistance genes in farmlands likely originated from mining areas. Bipartite network analysis additionally supported the potential migration of resistomes from mining sites to farmlands. Using an optimized risk assessment framework, we identified 14 high-risk mining ARGs, half of which had not been reported previously. These high-risk ARGs exhibited distinct geographic distributions between southern and northern regions, and many of their hosts remain uncharacterized.

To our knowledge, this study provided the first systematic, national-scale evidence of ARG dissemination potential from mining environments into agricultural ecosystems. By identifying previously overlooked high-risk ARGs, this research addressed critical knowledge gaps in evaluating resistomes from extreme environments and offered essential insights for managing ARG migration risks.

E-mail : huhaina11@163.com

**ABSTRACT**

Nutrient inputs are continuously altering desert steppe ecosystems; however, micronutrients—acting as key drivers of aboveground productivity and central mediators of belowground microbial community responses—have been relatively understudied in terms of their roles in shaping soil ecological processes in desert steppe. Therefore, we conducted a laboratory incubation experiment to investigate the effects of micronutrient (Mg, Fe, Mn, Cu, $ZnCl_2$, $ZnSO_4$) addition on the soil microbial community of a desert steppe under different incubation durations. The results showed that: (1) micronutrients exerted element-specific inhibitory effects on soil microbial diversity, with Mg, Fe, and Cu significantly reducing bacterial diversity, while Mn caused a persistent suppression of fungal diversity ($P < 0.05$); (2) microbial community responses to micronutrient additions displayed clear temporal dynamics. Although the overall succession followed a transition from r- to K-strategist communities, specific elements were able to regulate the intrinsic strategies of certain taxa. In particular, the addition of Mg or Fe delayed the response of typical r-strategist phyla (e.g., Proteobacteria), while inducing an earlier response of some K-strategist phyla (e.g., Acidobacteriota); and (3) redundancy analysis (RDA) indicated that specific micronutrients (e.g., Mg, Cu, and Zn) and the C:P ratio were key environmental factors driving fungal community succession, with their effects being time-dependent. During the early incubation stage (15 days), fungal communities were mainly driven by Mg and the C/P ratio, whereas during the later stage (90 days), Cu and Zn became the dominant drivers. Our results reveal that micronutrients play a decisive role in regulating soil microbial communities in desert steppe, providing critical theoretical support for improving nutrient management strategies and for enhancing ecosystem resistance to disturbance and the maintenance of ecosystem stability.

b20243211250@cau.edu.cn

**ABSTRACT**

Fertilization significantly alters soil physical and chemical properties, thereby indirectly affecting the nesting behavior and three-dimensional architecture of ground-nesting bees, yet the specific mechanisms remain unclear. This study investigated the responses of soil properties and the 3D burrow architecture of ground-nesting bees to long-term fertilization in the black soil region of Jilin, China. Using X-ray computed tomography (XRCT), we compared three treatments: no fertilizer (CK), conventional mineral fertilization (NPK), and integrated organic–inorganic fertilization (NPK+M).

Key findings indicate: (1) Fertilization significantly modified the topsoil (0-10 cm) environment, with both NPK and NPK+M treatments significantly reducing soil pH and increasing available phosphorus content and penetration resistance, while effects on bulk density, volumetric water content, and available potassium were not significant. (2) Fertilization selectively influenced burrow architecture. Both fertilized treatments significantly increased burrow depth (NPK: 26.31 cm; NPK+M: 26.58 cm) but reduced burrow abundance, particularly under NPK+M. NPK significantly increased the maximum burrow diameter, an effect not observed under NPK+M. Fertilization did not significantly affect average diameter, volume, or branch number, although the highest values for volume and branch number were recorded under NPK+M. (3) Soil layer-specific correlations were identified. In the 0-5 cm layer, available phosphorus and penetration resistance were negatively correlated with burrow abundance. In the 5-20 cm layer, bulk density positively correlated with burrow depth. In the deep layer (20-30 cm), bulk density, water content, and penetration resistance all positively correlated with burrow depth but negatively with burrow abundance. Burrow volume and branch number were strongly positively correlated across all layers.

This study demonstrates that fertilization does not directly alter the inherent structural characteristics of bee burrows, such as average diameter. Instead, it modifies soil acidity, nutrient availability, and physical compactness—particularly the penetration resistance of topsoil, thereby influencing the selection of nesting sites, including depth and abundance, as well as certain morphological traits like maximum diameter. Under the organic-inorganic combined fertilization treatment, a trade-off was observed: the structural complexity of individual burrows increased, while the nesting population declined. This suggests a potential balance between soil resource availability and habitat suitability. These findings provide important evidence for understanding how agricultural management practices, particularly fertilization strategies within conservation tillage systems, influence agricultural ecosystem functions through soil biological engineering pathways.

**ABSTRACT**

Fungi are pivotal to soil health, however, how do fungal types with different ecological strategies mediate soil functioning remains poorly understood. The responses of fungal ecotypes, defined by their adaptation as specialists, opportunists, or generalists in shaping community structure and function were illustrated through long-term (>10 years) nitrogen (N) gradient experiment across four regions with contrasting soil fertility. The results showed that overall fungal abundance increased with increasing soil fertility, while alpha diversity declined and the ecological niche of fungi narrowed. Critically, specialists and opportunists exhibited different performances in community, namely the relative abundance of specialists increased whereas that of opportunists decreased with increasing soil fertility. Specialists characterized by high energy metabolism and respiration became enriched in high-fertility soils, favoring the dominance of saprotrophic fungi following N addition. Such community shift drives functionality alteration, e.g., the diversity of carbohydrate metabolism and the capacity for cellulose degradation increased. A key specialist, *Mortierella elongata*, became dominant in high-fertility soils. In contrast, opportunists were suppressed by specialists in high-fertility soils, promoted pathogen abundance via decomposing amino acid rather than intervening degrading cellulose in low-fertility soils, especially under N enrichment. By comparison, generalist with low abundances remains stable across all soils. Collectively, organic carbon dynamics and eventually soil fertility were changed by fungi with different ecological strategies, advancing mechanistic understanding of how fungi communities maintain and modulate soil fertility.

**ABSTRACT**

Sandy soil is typified by loose structure, poor aggregation, low organic carbon content, and limited nutrient and water-holding capacities. Organic compost application represents an effective ameliorative strategy for this kind of soil, with its effects interacting with tillage practices. Nevertheless, studies examining these interactions remain relatively limited in sandy soil ecosystems in Chiping District, Liaocheng City, Shandong Province. This study investigated the effects of compost application under three tillage practices—subsoiling (SS),deep ploughing (DP),and rotary tillage (RT) on the composition and structure of bacterial and fungal communities in the soil. The results insight for targeted sandy soil improvement and sustainable farm management.

Compost application, in combination with tillage, modified the community composition of both bacteria and fungi across soil layers. In the 0–20 cm layer, compost-amended treatments significantly increased the abundance of the bacterial phylum Gemmatimonadota while reducing the relative abundances of the bacterial phyla Pseudomonadota and Chloroflexi and the fungal phylum Basidiomycota. In the 20–40 cm layer, compost addition similarly enriched the bacterial phylum Gemmatimonadota and the fungal phylum Ascomycota. Moreover, compost application together with tillage practices noticeably affected the alpha diversity of both soil bacterial and fungal communities.

*j.milkereit@soils.uni-kiel.de

**ABSTRACT**

Anthelmintics, such as moxidectin (MOX), are widely used to treat or prevent gastrointestinal parasites in livestock and companion animals. Up to 77% of the dose applied to animals is excreted via feces and can ultimately enter the soil environment either through grazing animals or application of manure. Based on its wide application and potential ecotoxic effects the impact of anthelmintic drugs on non-target organisms has been widely studied and there is evidence for negative effects on seed germination and dung dwelling fauna. However, effects on free-living nematodes, an organism group with soil food web interactions at every trophic level and great ecological importance are insufficiently addressed with a focus on quantitative measurements. We established a pot experiment to compare nematode communities in soils with 0.25, 0,5 or 1 mg MOX with control soils in five replicates respectively. Nematodes were counted and identified to genus level. Additionally, microbial biomass carbon (MBC) and soil nitrogen were measured to identify possible interactions of nematode abundances with resource availability and soil functioning. Nematode indices were used as indicators of soil disturbance. Similar to previous studies overall nematode abundance was not affected by anthelmintics. However, the community composition was altered with a decrease in c-p3 (colonizer-persister) nematodes, which are characterized by longer life cycles and greater sensitivity to disturbance. Opportunistic nematodes with faster reproduction rates and greater disturbance tolerance (≤c-p2) dominated the communities with MOX and correlated with MBC. A decreased Maturity 2-5 index and Structure index indicate a toxic disturbance by MOX. The genus richness of the communities was not affected but the evenness was reduced with 0.25 and 0.5 mg MOX compared to controls. While soil mineral N was not affected, we found that total N was reduced with MOX suggesting changes in soil N mineralization. Our results show that quantitative measurements alone are not sufficient to assess the effects of medical compounds entering the soil environment but rather the focus should be on qualitative measurements that capture potential species loss and associated changes in ecological functioning of the soil communities.

*[2] Embrapa Cerrados (Brasília, Brazil)*

*[3]Fundação MT (Rondonópolis/MT, Brazil)*

*guilherme.chaer@embrapa.br

**ABSTRACT**

A growing body of evidence suggests that soil organic carbon (SOC) and enzymatic activity exhibit biochemical equilibrium in natural and long-term managed systems. Building on this principle, the Soil Carbon Trend Index (SCTI) was developed as part of the BioAS technology to assess the trajectory of SOC in response to land use and management changes. The SCTI compares the enzymatic sufficiency level—based on the activity of arylsulfatase (ARIL) and β-glucosidase (GLI)—with the SOC content, both normalized using texture-specific scoring curves for Brazilian Cerrado Oxisols. The index ranges from –1 to +1, where values below zero indicate a tendency for SOC loss, values above zero indicate SOC accumulation, and values near zero reflect biochemical equilibrium. The SCTI was tested in a long-term field experiment (2008–2024) in Itiquira, Mato Grosso (Brazil), evaluating the transition from conventional soybean monoculture to no-till with soybean–brachiaria rotation. Between 2016 and 2020, under conventional management, ARIL and GLI levels were 18 and 32 µg $pNP.g^{-1}.h^{-1}$, respectively, with SOC at 15.5 $g.dm^{-3}$ and an average SCTI of –0.15. Following adoption of conservation practices in 2020, ARIL and GLI rose to 68 and 182 µg $pNP.g^{-1}.h^{-1}$, while SOC increased to 17.4 $g.dm^{-3}$ by 2024. The SCTI shifted to 0.14 in 2022 and 0.17 in 2024, capturing the shift toward carbon accumulation. These results confirm the sensitivity of enzyme activity to management changes and the SCTI's ability to anticipate SOC trends. Ongoing research aims to relate SCTI values not only to the direction of change, but also to the magnitude and rate of SOC variation across soil types and land use systems. The SCTI offers a promising, low-cost biochemical indicator for regional soil health monitoring and carbon reporting.

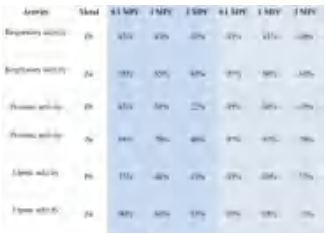
# Assessment of the Stabilizing Effect of Compost and Phosphogypsum on the Metabolism of Bacillus subtilis and Pseudomonas putida in Sod-Podzolic Soil Contaminated with Lead and Zinc

**Anton Nikitenko[1], Ivan Vasenev[1], Peter Vasenev[1], Dmitry Morev[1]**

*Department of Ecology, Russian State Agrarian University - Moscow Timiryazev Agricultural Academy (RSAU - MTAA), Moscow, Russian Federation*

e-mail: brokendrummachine@mail.ru



**ABSTRACT**

The work summarizes data from laboratory experiments on the inhibitory effect of Pb and Zn (0.1; 1; 2 MPC. Pb - 32 mg/kg, Zn - 23 mg/kg) on the metabolic activity of Bacillus subtilis and Pseudomonas putida in anthropogenically degraded sod-podzolic soil, with an assessment of the stabilizing effect of compost from quail manure and phosphogypsum. A dose-dependent suppression of respiratory, protease, and lipase activity was established. Compost and phosphogypsum reduce toxicity, increasing the activity of microorganisms, confirming their potential for bioindication of heavy metal pollution. The specified metals inhibit key enzymatic and respiratory processes in microorganisms (Bacillus subtilis and Pseudomonas putida), which play an important role in the degradation of organic substances. The application of organic ameliorants, such as compost from quail manure and phosphogypsum, promotes the immobilization of metals and stimulation of microbial activity (Tab.1).

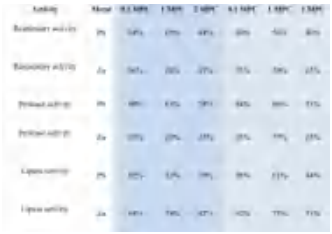
The aim of the study was to analyze the inhibitory effect of increasing concentrations of Pb and Zn on the metabolic activity of Bacillus subtilis and Pseudomonas putida in anthropogenically degraded sod-podzolic soil with an assessment of the stabilizing effect of compost and phosphogypsum. A dose-dependent inhibition was observed.

**Key words:** *BACILLUS SUBTILIS* (L),*PSEUDOMONAS PUTIDA* (L), LEAD, ZINC, MICROBIAL BREATHING, BIOINDICATION.

**Table 1:** metabolic activity of Bacillus subtilis and Pseudomonas putida without ameliorants (% of control)

With the use of ameliorants, a stabilizing effect was observed, reducing inhibition. (Tables 2-3)

**Table 2:** metabolic activity of Bacillus subtilis and Pseudomonas putida with compost (% of control)



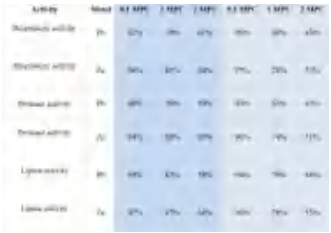


**Table 3:** metabolic activity of Bacillus subtilis and Pseudomonas putida with phosphogypsum (% of control)

Conclusions: Pb/Zn suppress metabolism in a dose-dependent manner. Ameliorants stabilize the metabolism of microbiota, reducing inhibition.

**ABSTRACT**

Soil biodiversity underpins key ecosystem functions, yet its potential to serve as a scalable indicator of soil health and plant productivity remains underexplored. In this study, we investigated whether fine-scale microbial patterns associated with yield within a single agricultural field can be generalized to predict plant growth across global ecosystems. High-resolution soil sampling was conducted on a maize field in Germany, coupling 16S rRNA sequencing with spatially explicit yield measurements. Using machine learning (LASSO regression), we identified a set of 26 bacterial genera whose abundances explained ~65% of local yield variation through cross-validation. These genera represent diverse taxonomic groups and include consistently yield-associating taxa such as Hyphomicrobium, Reyranella, Luedemannella, Aeromicrobium, Flavitalea, and Ellin6055.

To test the robustness and scalability of these local microbial indicators, we validated the model across seven independent, globally distributed datasets encompassing croplands, grasslands, and pastures. Despite differences in environmental conditions, sequencing methods, and productivity metrics (yield, soil health indices, and NDVI-based net primary production), the locally trained model successfully predicted up to 37% of global vegetation variation. Most of the key genera displayed coherent associations with productivity across continents, demonstrating that certain soil bacterial signatures respond predictably to plant growth independent of biome, climate, or pH gradients. Additional analyses controlling for major climatic variables showed that these associations persist beyond broad environmental drivers, suggesting that microbial traits linked to resource turnover, carbon cycling, or plant–microbe feedback may be intrinsically tied to ecosystem productivity.

These findings provide evidence for a globally conserved set of soil bacterial indicators that capture meaningful variation in plant growth and soil function. They highlight the potential of microbiome-based modelling as a powerful tool for high-resolution soil health assessment, capable of integrating biodiversity metrics with agronomic and ecological outcomes. By bridging local microbial processes with global patterns, this work advances efforts to develop mechanistic, scalable, and biologically grounded indicators for sustainable soil management.
